Abstract

Background: With the burden of prostate cancer, it has become imperative to exploit cost-effective ways to tackle this menace. Women have demonstrated their ability to recognize early cancer signs and it is therefore relevant to include women in strategies to improve the early detection of prostate cancer. This systematic review seeks to gather evidence from studies that investigated women's knowledge about; (1) the signs and symptoms, (2) causes and risk factors, and (3) the screening modalities of prostate cancer. Findings from the review will better position women in the fight against the late detection of prostate cancer.

Methods: The convergent segregated approach to the conduct of mixed-methods systematic reviews was employed. Five databases namely; MEDLINE (EBSCOhost), CINAHL (EBSCOhost), PsycINFO (EBSCOhost), Web of Science, and EMBASE (Ovid) were searched from January 1999 to December 2019 for studies conducted with a focus on the knowledge of women on the signs and symptoms; the causes and risk factors; and the screening modalities of prostate cancer.

Results: Of 2201 titles and abstracts screened, 22 full-text papers were retrieved and reviewed, and 7 were included: 3 quantitative, 1 qualitative, and 3 mixed-methods studies. Both quantitative and qualitative findings indicate that women have moderate knowledge of the signs and symptoms; and the causes and risk factors of prostate cancer. However, women recorded poor knowledge about prostate cancer screening modalities or tools.

Conclusions: Moderate knowledge of women on the signs and symptoms, and the causes and risk factors of prostate cancer were associated with education. These findings provide vital information for the prevention and control of prostate cancer and encourage policy-makers to incorporate health promotion and awareness campaigns in health policies to improve knowledge and awareness of prostate cancer globally.

Systematic Review registration number: Open Science Framework (OSF) registration DOI: https://doi.org/10.17605/OSF.IO/BR456

Background

Prostate cancer (PCa) is the most common non-skin cancer occurring in men and is accountable for 3.8% of all mortality caused by cancer in men (1, 2). According to the GLOBOCAN, 2018 database, it is estimated that it is the fifth primary cause of cancer death in men globally. It further reported that the highest mortality rate is found in the Caribbean and Southern African men worldwide (1, 3). A recent study by Yeboah-Asiamah et al. reported that PCa was the second most common cancer in areas such as Australia, the United States, and New Zealand (4).

Though fewer than 30% of all incidence of PCa are from developing countries, these countries have previously been estimated to have the highest mortality from PCa due to late diagnosis (5, 6). Although sub-Saharan Africa (SSA) has a low rate of the disease, the incidence is projected to increase if screening is encouraged (7). Hence, PCa remains a vital public health concern in both developed and developing countries.

The Centers for Disease Control and Prevention (CDC) in North America, organized a workshop with the motive to explore strategies to control and prevent the disease based on the increasing incidence and mortality rate of PCa (8). To address mortality rates related to the disease, participants recommended strategies to improve PCa awareness (8). Also, as documented by many studies, PCa incidence is a direct reflection of the rate at which high-risk groups screen for the disease (4, 9). In Europe, early screening was attributed to a 20% reduction in PCa mortality rate (10). Although there is evidence suggesting a reduction in PCa mortality due to early screening, a United States (US) study did not highlight a reduction in mortality (11). The prostate-specific antigen (PSA) test and the digital rectal examination (DRE) are useful screening tools, although initial controversies were surrounding the use of these tools (12). Because of overlap in PSA levels in men with prostatitis, benign prostatic hyperplasia, and PCa, it was assumed that PCa cannot be screened using the PSA test (13). Catalona et al. demonstrated that PSA could be utilized as a screening tool for PCa and it has widely been adopted (14). DRE is the only procedure whereby physicians can examine part of the prostate gland (15). The findings are only based on the physician impression, hence poor inter-rater reliability and also a limitation to the palpable region of the prostate gland (15). However, DRE sometimes detects PCa in men with PSA, 4.0 ng/mL (16). Regardless of the controversial nature of screening and the potential for early screening to reduce mortality, studies support the need to encourage screening (4, 12).

Women have essential characteristics that make them better managers of family health as compared to men. Therefore, it is not surprising that there is evidence positioning women as individuals who make adequate observations about the health of their partners (9, 17). In promoting the early detection of PCa, women have been documented to observe the slightest symptoms presented by their partners and push them to seek medical attention (9, 18). In a study conducted by Blanchard et al., it was recommended that efforts must be made to actively involve women in improving the timely detection of PCa through the closure of knowledge-gaps (19).

Also, men admit seeking out their wives' opinions as sources of health information (20). In the context of the early detection of PCa, women can play various roles such as information seekers, advocates, health advisors, and support persons (21). Therefore, there is the need to gather
current evidence about women’s knowledge of PCa as the findings will be vital in equipping women to contribute towards the early detection of the disease.

In light of the availability of limited evidence addressing the awareness of women on prostate cancer, this review will seek to combine quantitative and qualitative data to increase the validity of findings through data triangulation as recommended by Caruth and supported by Lizarondo et al. (22, 23). Thus, this review seeks to map out current evidence regarding women’s awareness of PCa under the scopes of; 1) signs and symptoms, 2) risk factors and causes, and 3) screening guidelines.

**Methodology**

The Joanna Briggs Institute (JBI) reviewer’s manual for the conduct of mixed-methods critical appraisal and synthesis formed the backbone of the study (23). With guidance from the JBI manual, a protocol was developed to guide the review process according to the convergent segregated approach (23). The respective DOIs of the review protocol and review, registered with the Open Science Framework (OSF), are https://doi.org/10.17605/OSF.IO/EYHF2 and https://doi.org/10.17605/OSF.IO/BR456.

**Inclusion criteria**

We considered studies that were published in English and peer-reviewed journals between January 1999 and December 2019. Included studies were selected from primary research of any methodology; and explored awareness on signs and symptoms, causes and risk factors, and screening of prostate cancer. Studies that were conducted among women regardless of the geographical location were included. Studies that were mainly conducted in men were excluded in addition to studies not published in the English language.

**Information sources and search strategy**

An initial explorative search in PubMed founded search terms in preparation for comprehensive electronic search. The selected search terms were combined with Boolean operators for a comprehensive electronic search in MEDLINE (EBSCOhost), CINAHL (EBSCOhost), PsycINFO (EBSCOhost), Web of Science, and EMBASE (Ovid) as “(prostate cancer ) AND (awareness OR knowledge) AND (signs OR symptoms) AND (risk factors OR causes) AND (screening) AND (women)”. The search strategy (Appendix 1), so developed, was utilized by the first (EW) and second (KBM) reviewers to independently conduct a literature search as outlined in the review protocol (24).

**Selection of studies**

The first and second reviewers, being guided by the developed review protocol, singularly screened and compared the titles and abstracts of the literature search outcomes to a developed standard (Appendix 2). Studies that successfully passed the initial stage of screening were subjected to the independent full-text reading by EW and KBM before consideration for data extraction. Lastly, hand-searching and snowballing on references of selected articles were done to find eligible studies in the grey area. There were no disagreements between EW and KBM. Hence, the third reviewer (ABBM) assessed the studies before data extraction was conducted by the lead author according to the JBI data extraction tools outlined in the review protocol (24). The characteristic of studies that successfully went through the data extraction, the key findings that were extracted, and a summary of the study selection process are detailed respectively (Table 1, Table 2, and Fig. 1).

<td>Knowledge, Attitudes and Beliefs of Women about the Importance of Prostate Cancer Screening (Blanchard et al., 2005).</td>
<td>1. The mean score for women's knowledge about prostate cancer and screening guidelines was determined to be 6.99 ± 3.54 out of 15 points. 2. Educational level and income were discovered to have increased the mean score for women's knowledge. 3. Women who disclosed their familiarity with cancer of the prostate and available screening recommendations recorded higher scores in knowledge assessment. 4. Only 54.3% of women knew about the asymptomatic presentation of prostate cancer in early stages. 5. About 37% of women failed to recognize age as a risk factor for prostate cancer. 6. 83.9% of women were of the known that men, symptomatic or not, should screen for prostate cancer. 7. 54% of married and 42% of single women recognized the early detection of prostate cancer as the key importance of screening. 8. Married (41%) and single (32%) women agreed that men feared prostate cancer screening results as well as the application of the digital rectal examination for screening.</td>
<td>Women are not knowledgeable about prostate cancer. An educational intervention model, targeting women, could equip women to contribute to the early detection of prostate cancer by encouraging men to screen routinely for the disease.</td>
<td>1. Women might not have documented true responses to questionnaire items since a self-reporting technique was employed in the study. 2. The study was limited to only women fluent in the English language and hence, findings could not be extended to cover all women in New Orleans. 3. The use of the convenience sampling method in the study exposed the study to participants selection bias and hence, a negative impact on the generalization of study findings.</td>

### STUDY TITLE

#### FINDINGS

1. Leverage the Family Influence of Women in Prostate Cancer Efforts: Targeting African American Men (Okoro, Rutherford, & Witherspoon, 2018).

   1. 100 women each from 7 countries were involved in the study. 2. 28% of female respondents spontaneously included prostate cancer in their list of available cancers whilst 69%, who didn't initially list prostate cancer, agreed to the existence of the disease when asked a closed-ended question. 3. Women in the United Kingdom (40%), United States (20%), France (23%), Germany (24%), Italy (21%), Spain (26%), and Sweden (39%) were spontaneously aware of prostate cancer. When prompted, additional respondents included symptoms, and risk factors of prostate cancer. Women were able to identify the signs and symptoms of prostate cancer. 4. Women in Spain (36%), the United States (35%), Italy (23%), Sweden (22%), the United Kingdom (17%), France (17%), and Germany (9%) recognized PSA as a prostate cancer screening tool. 5. 20% of women in the United States, 14% in France, 8% in Spain, 6% in the United Kingdom, 6% in Germany, 5% in Italy, and 2% in Sweden recognized PSA as a prostate cancer screening tool. 6. Mistakenly, 37% of women in Spain, 22% in Italy, 17% in France, 13% in the United Kingdom, 10% in Germany, 11% in Sweden, and 5% in the United States recognized the use of urine as a prostate cancer screening sample. 7. The inability of women to recognize at least a prostate cancer screening tool followed the trend: Germany (71%), Sweden (60%), the United Kingdom (56%), the United States (53%), France (52%), Italy (44%) and Spain (41%).

#### CONCLUSION

The recognition of the basic prostate cancer screening tools by women was very low. The general awareness of prostate cancer was lacking in women. To promote the early detection of prostate cancer in an attempt to reduce mortality, and educational intervention targeting women is needed.

#### LIMITATIONS

1. The study failed to indicate the percentage of women who were able to identify the signs and symptoms, and risk factors of prostate cancer. 2. The number of participants from the various countries was relatively small to promote the generalizability of results. 3. Respondents might have given socially approved responses since data collection was through a telephone interview. 4. The validity and reliability of the questionnaire were not determined in the study population.

1. Women disclosed that prostate cancer may occur in men who are or greater than 65 years old. However, women were not sure if a diet has caused a reduction in the age at which men develop prostate cancer. 2. During the FDG, some women agreed that prostate cancer screening starts when men celebrate their 40th birthday. 3. The use of blood as a screening sample for prostate cancer detection was mentioned by women. However, women reported the need for a physical body examination in addition to blood analysis.

The knowledge women possess about prostate cancer screening have appreciable gaps. Educating women on prostate cancer screening is of equal importance as male prostate cancer education.

1. Results have low generalizability due to the utilization of the convenience sampling strategy. 2. Validity and reliability studies of the FGD questions were not done in the study population. 3. The target number of study subjects needed for the FGD was not met. Hence, the study sample was inadequate.

Quality assessment

As described in the review protocol (24), the methodological quality assessment tool (Appendix 3) was adopted and modified for this review (25). The tool appraised the studies’ quality based on the studies sample representativeness, response rate, reliability, and validity of the data collection tool. The tool was modified to suit the results from the included studies. A score was calculated, and the quality of the studies was classified as weak (0–33.9%), moderate (34–66.9%), or strong (67–100%). Eligible records were subjected to independent quality assessment by EW and KBM. Methodological quality outcomes were not grounds for exclusion.

Synthesis and integration of findings

The review findings were subjected to the convergent segregated approach to synthesis and integration according to the developed review protocol (24). A narrative synthesis was separately performed for qualitative and quantitative findings. The results were finally integrated.

Results

Conducting the review, according to the developed protocol, yielded 2200 studies results. A detailed citation screening led to an additional study, which increased the total studies to 2201. Regarding the summary of the study selection process (Fig. 1), 1672 studies were obtained after 529 duplicates were removed from the pool of data. Post-titles and abstracts review excluded 1650 studies leaving 22 studies. The 22 studies were further reduced to 7 after a full-text reading resulted in the exclusion of 15 studies.

Characteristics of included studies

The data extracted from the seven (7) studies are detailed (Table 1). The publication years ranged from 2003 to 2018 with 5 studies having been conducted in the United States. One of the studies was a multicenter study that involved multinationals (26). The study with the highest female participants (4040 women) was conducted in Spain (27). Webb et al. recruited the lowest sample size, 14 women (28). A total of 5634 women were involved in the 7 studies. Two studies were solely conducted in women, three included other diseases, and two did not disclose study duration.

Quality of included studies

According to the scoring scheme of the quality assessment tool (Appendix 3), two studies (27, 28) were evaluated as moderate-quality whilst five studies were evaluated as strong quality. None of the studies were excluded based on methodological quality assessment outcomes. There was no disagreement between EW and KBM.

Review findings

Study findings, presented in Table 2, were heterogeneous. Quantitative studies indicate that women knew about the existence of PCa. In exploring qualitative evidence, women exhibited knowledge of PCa. Therefore, both arms of the review are supportive of each other.

Women had moderate knowledge about the signs and symptoms of PCa drawing from quantitative findings. The asymptomatic nature of early staged PCa; and women moderately knew urinary symptoms such as urinary frequency, difficulty in urinating, and dysuria. Qualitative studies
indicate that women were aware of signs and symptoms such as urinary frequency, difficulty in urinating, glandular enlargement of the prostate, and erectile dysfunction. Hence, quantitative and qualitative findings revealed that women moderately knew the urinary symptoms of PCa.

Quantitative studies indicate an average score of women on knowledge of risk factors of PCa. Risk factors women knew were increasing age, presence of a first-degree relative, being genetically linked to Africa, and excessive truncal obesity. Qualitative evidence recognized all risk factors documented by the quantitative findings except truncal obesity. Also, identified risk factors included poor diet, inadequate exercise, stressful lifestyle, poor screening habits, cigarette smoking, and poor access to quality healthcare. Women wrongly reported sexual orientation and frequent sexual activity as risk factors. Therefore, qualitative findings confirm the quantitative claim that women have shared knowledge about the risk factors of PCa.

Quantitative studies indicate that women had poor knowledge about PCa screening. Although it was reported that women knew about PSA and DRE, knowledge scores were significantly low. Also, women poorly recognized urine as a screening sample, PSA as an exclusive diagnostic tool, and failed to identify more than one screening tool. Qualitative studies respectively reported PSA and blood as a screening tool and sample. Colonoscopy was wrongly reported as a PCa screening tool. Conclusively, both arms of the review reported women knew about PSA and had poor knowledge about PCa screening.

Discussion

The heterogeneity of the study findings warranted the synthesis as a narrative (23, 29). The convergent segregated approach was employed according to the recommendation of the JBI reviewer’s manual (23).

Generally, from the quantitative evidence, women knew about prostate cancer (19, 26, 30, 31). The knowledge of women was found to have increased with educational and financial status (19); and disease familiarity (19, 31). The awareness of women about the existence of PCa increased when the disease was mentioned compared to an initial request for women to list cancers (26). Qualitative evidence showed that women were aware of PCa (18, 30). They appreciated and specifically requested for PCa education partly because they could not tell the location of the prostate gland (18). Thus, quantitative and qualitative evidence indicates that women know about PCa. Women’s awareness could be due to their role in family health management and the possible health-seeking behavior of educated and financially strong women. As persons are faced with the experiences of a health condition, they will seek to make sense of this illness by acquiring knowledge (32), experiences, and beliefs; hence this theory might explain the improved awareness of women who were familiar with the disease.

Most of the quantitative studies indicate that women are aware of the asymptomatic nature of early-stage PCa (19, 30, 31). Symptoms that women had a fair knowledge about included urinary frequency, difficulty in urinating, and dysuria (31). Findings from one of the qualitative studies indicate that women fairly recognized urinary frequency, difficulty in urinating, glandular enlargement of the prostate, and erectile dysfunction as signs and symptoms of PCa (18). Being familiar with the disease may explain the awareness of women of the urinary symptoms associated with PCa.

According to Okoro and colleagues’ quantitative study, although knowledge of PCa was not adequate, women knew associated risk factors such as being a first-degree relative, being a man of African descent, and excessive truncal obesity (30). Blanchard et al. also documented women's recognition of increasing age as a PCa risk factor (19). One of the qualitative studies indicates women knew increasing age could increase a man's chance for PCa development (18, 28). Other causes and risk factors women identified included poor diet, inadequate exercise, stressful lifestyle, family history of the disease, being of African descent, poor screening habits, cigarette smoking, and poor access to quality healthcare (18). Eroneously, one study reported that women perceived sexual orientation and frequent sexual activity as risk factors (18). Both quantitative and qualitative findings documented women knew increasing age, family history, and African descent as PCa risk factors.

Quantitatively, women’s responses to queries about PCa screening was poor (26, 31). Some women were unable to recognize at least a PCa screening tool whilst others mistakenly recognized urine as a suitable sample for PCa screening (26). According to Okoro et al. the majority of women exclusively tagged PSA elevation as a basis for PCa diagnosis (30). This, therefore, calls for extensive education because benign prostatic hyperplasia, prostatitis, and PCa usually present with elevated PSA (13). Evidence from qualitative findings indicated women knew physical examination must augment blood analysis (28). Also, women mentioned PSA and colonoscopy as screening tools (18). The results from included qualitative studies confirmed that women had poor knowledge about PCa screening. The mention of colonoscopy as a screening tool further supports a lack of adequate knowledge about PCa screening.

This critical appraisal and synthesis revealed over the 20 years of study search, only four studies out of the seven included studies investigated all the outcomes of interest. Two studies did not investigate women’s awareness of the signs and symptoms (27, 28) and the causes and risk factors (27, 31) of PCa. Therefore, although quantitative and qualitative findings were supportive of each other, studies investigating the causes and risk factors, as well as the signs and symptoms of PCa, were lacking.
Recommendations For Practice

From the review findings, it is recommended that PCa control programs should also focus on educating women. Clinicians and public health practitioners should include women in prostate cancer health promotion. Women should be encouraged to attend PCa clinics with their male significant others suffering from the disease and the effect of this strategy in reducing PCa mortality rate investigated.

Recommendations For Research

Further studies are recommended to investigate the knowledge of women living in low and middle-income countries (LMIC) about PCa. Such studies should focus extensively on the knowledge of women on PCa screening. Also, it is recommended for research to develop and pilot a PCa educational intervention model, applicable to women to reduce the burden of the disease. This tool should be cultural-specific for easy acceptance and recognition. Also, current evidence on the willingness of women to offer social support to men with PCa should be investigated.

Study Limitations

The various restrictions that were imposed on the literature search included a search range from January 1999 to December 2019, a search into only 5 databases, and the outright exclusion of non-English publications.

Other limitations were the exclusion of studies conducted in women who received education on prostate cancer, healthcare professionals, healthcare students, and college/university students, and further exclusion of studies that involved (LGBTQ) participants.
