## Abstract

We present first results of UT1-UTC determinations using the VLBI Global Observing System (VGOS). During December 2019 through February 2020 a series of 1 hour long observing sessions were performed using the VGOS stations at Ishioka in Japan and the Onsala twin telescopes in Sweden. The data of this VGOS-B series were correlated, post-correlation processed, and analysed at the Onsala Space Observatory. The derived UT1-UTC results were compared to corresponding results from standard legacy S/X Intensive sessions (INT1/INT2), as well to the final values of the International Earth Rotation and Reference Frame Service (IERS), provided in IERS Bulletin B. The VGOS-B series achieve 3-4 times lower formal uncertainties for the UT1-UTC results than standard legacy S/X INT series. Furthermore, the root mean square (RMS) agreement with respect to the IERS Bulletin B is 30-40 % better for the VGOS-B results than for the INT1/INT2 results.

## Keywords

UT1-UTC, VLBI Intensives, VLBI Global Observing System (VGOS), VGOS twin telescopes

## Introduction

Geodetic Very Long Baseline Interferometry (VLBI) (Sovers et al 1998) is to date the only space geodetic technique that can observe all earth orientation parameters (EOP). This is primarily due to that VLBI directly observes natural radio sources in the International Celestial Reference Frame (ICRF, Charlot et al 2020) with radio telescopes on the surface of the earth, i.e. in the terrestrial reference frame (ITRF, Altamimi et al 2016). The EOP are the transformation parameters between these two frames. The EOP that is most difficult to predict due to rapidly varying geophysical excitation is the daily rotation of the earth. It is usually reported as difference between UT1 and Universal Time Coordinated (UTC), and a precise and accurate monitoring of this parameter is of great importance for satellite navigation systems and satellite orbit determination (Bradley et al 2016).

The International VLBI Service for Geodesy and Astrometry (IVS) (Nothnagel et al 2017) therefore organises dedicated regular observation sessions to determine UT1-UTC, so that the International Earth Rotation and Reference Frames Service (IERS) can produce precise, accurate and reliable data series of

1 UT1-UTC with low latency that scientific users and society at large can use. These IVS session are the  
2 so-called IVS Intensive sessions (INT), which have been observed routinely since decades with the legacy  
3 S/X VLBI system that the IVS organises. The INT series make use of long east-west oriented baselines  
4 due to their high sensitivity for UT1. The two main series are INT1, usually observed on weekdays on the  
5 baseline between Kokee (Hawaii, US) and Wettzell (Germany), and INT2, usually observed on weekends  
6 on the baseline between Wettzell (Germany) and Ishioka (Japan). Before Ishioka was involved in INT2,  
7 instead the station Tsukuba (Japan) was part of this series. There is also a third INT series, INT3,  
8 which observes on Monday mornings usually with a three-station network. During the years, a number of  
9 variations were seen in terms of which stations were involved, mainly due to replacing stations for times  
10 of station outages due to e.g. maintenance.  
11

12 While the standard INT are observed with the IVS legacy S/X system, during the last years new stations  
13 for the next generation VLBI system called the VLBI Global Observing System (VGOS) have been  
14 constructed. VGOS makes use of very fast slewing telescopes with broadband receiving systems covering  
15 four frequency ranges, and dual polarization (H/V) capability (Petrachenko et al 2009; Niell et al 2018).  
16 Ishioka (Wakasugi et al 2019) is one of these stations. Furthremore, it can exchange the receiving system,  
17 i.e. Ishioka can be used for some months of the year as legacy S/X station and for other months of the year  
18 as VGOS station. Another example of VGOS stations are the Onsala twin telescopes (OTT, Haas et al  
19 2019), which are the currently only operational VGOS twin telescopes. Both Ishioka and the OTT are  
20 participating routinely to the IVS VGOS operations series (VO). In discussions with the IVS coordinating  
21 center in late 2019, the idea came up to start test observations in order to make use of VGOS for Intensive  
22 sessions and thus explicitly UT1-UTC determination. Using the Onsala twin telescopes in this so-called  
23 VGOS-B series allows simultaneous UT1-UTC determination with two parallel long east-west baselines  
24 connecting to Ishioka.  
25

### 26 **Scheduling and observing the VGOS-B sessions**

27 For the period December 2019 through February 2020 in total 12 VGOS-B sessions were scheduled. The  
28 scheduling was done with the software VieSched++ (Schartner and Böhm 2019) involving the VGOS  
29 stations ISHIOKA (Is) in Japan and ONSA13NE (Oe) and ONSA13SW (Ow) in Sweden. The schedules  
30 were prepared to be simultaneous to standard INT1 observations. During scheduling, special emphasis  
31 was given to include observations at the corners of the mutually visible sky since these observations are  
32

1 known to provide the most impact on the precision of the derived UT1-UTC results (Uunila et al 2012;  
2 Gipson and Bayer 2015). To achieve this, a special scheduling algorithm was used. The schedule starts  
3  
4 by observing a source at one of the two corners of the mutually visible sky, followed by scans selected  
5  
6 using standard geodetic scheduling optimization. Every ten minutes, the algorithm forces a scan of a  
7  
8 source located in one of the corners, alternating between the two possibilities. Therefore, it is ensured  
9  
10 that observations at the corners of the mutually visible sky are well represented in the schedule.

11  
12 Due to the modern and fast-slewing VGOS telescopes, the number of scheduled observations per baseline  
13  
14 was more than 50 during the 1 hour long sessions. This is significantly more than the usually 20-  
15  
16 25 observations during 1 hour long INT1 and INT2 sessions with legacy S/X stations. We note that  
17  
18 the VGOS-B sessions analysed in this paper were scheduled assuming standard VO-session recording  
19  
20 overheads, such as buffer-flush times needed for Mark6-recording systems, which limit the number of  
21  
22 scans per unit time. Future VGOS-B sessions will be further optimised for the Is-Oe/Ow systems, which  
23  
24 do not have these overheads, and can therefore schedule  $\sim 100$  observations per baseline per hour, fully  
25  
26 utilising the fast slewing speed.

27  
28 Table 1 lists these 12 VGOS-B sessions and their INT1 counter parts, including the stations involved.  
29  
30 From simulations with VieSched++ the formal uncertainties of the UT1-UTC estimates are 4-5  $\mu\text{s}$  for  
31  
32 the VGOS-B sessions, while they are a factor of 2-3 worse for the legacy S/X intensive schedules.  
33  
34 Unfortunately, during four of the twelve VGOS-B sessions technical problems occurred at Ishioka, so  
35  
36 that the observed raw data were not complete, see the comments in the table.  
37  
38  
39  
40  
41

## 42 **Correlation and post-correlation analysis**

43  
44 The observed raw data of the Ishioka station were transferred electronically to the VLBI correlator  
45  
46 at the Onsala Space Observatory. The software correlator DiFX version 2.6.1 Deller et al (2011) was  
47  
48 used for correlation and the Haystack Observatory Postprocessing System (HOPS, MIT/Haystack 2020)  
49  
50 version 3.21 was used for the post-correlation analysis. The data were processed according to the VGOS  
51  
52 Data Processing Manual (MIT/Haystack 2019). This included forming the pseudo-stokes I polarisation  
53  
54 product, from the recorded H and V data, to account for parallactic-angle differences. Both H and V  
55  
56 are required for this process, and therefore the single-polarisation Is-data (see Table 1) were omitted  
57  
58 from post-processing. The short (75 m) baseline Oe-Ow suffered from disturbing local radio frequency  
59  
60 interference (RFI). The full VGOS band-A, and a few channels in other VGOS-bands, were therefore  
61  
62  
63  
64  
65

Table 1. : VGOS-B sessions in December 2019 through February 2020, and their simultaneously observed INT1 counterparts. The stations are ISHIOKA (Is), ONSA13NE (Oe), ONSA13SW (Ow), KOKEE (Kk), WETTZELL (Wz), SVETLOE (Sv) and MK-VLBA (Mk).

Code	Stations	Comment	Code	Stations

B20037	Is-Oe-Ow		I20037	Kk-Wz-Sv
B20044	Is-Oe-Ow	(Is-data: only H-polarization)	I20044	Kk-Wz
B20048	Is-Oe-Ow	(Is-data: only H-polarization)	I20048	Mk-Wz
B20055	Is-Oe-Ow	(Is-data: only H-polarization)	I20055	Kk-Wz

excluded from Oe-Ow post-processing, thus deteriorating the delay accuracy on this baseline. Finally, the VLBI delay observations were exported to vgosDb format (Bolotin et al 2015). The corresponding tools of the  $\nu$ Solve software package version 0.7.1 (Bolotin et al 2012) were used to calculate and add the theoretical delays (vgosDbCalc) as well as the supplemental data from the observing station logfiles (vgosDbProcLogs). We note that while Oe and Ow are equipped with Cable Delay Measurement Systems (CDMS) which stores delay corrections in the observing logfiles, Is currently does not measure such corrections. Therefore, proxy-cable corrections were derived using the Is phase-calibration data as described in VGOS Data Processing Manual (MIT/Haystack 2019).

### Data analysis and results

The geodetic data analysis was performed with the ASCoT software (Artz et al 2016). We analysed both the VGOS-B sessions, as well as all INT1 and INT2 sessions in the time range December 2019 through

1 February 2020. As mentioned above, only eight of the twelve VGOS-B sessions could be analysed, since  
2 during four of these sessions some technical problems had occurred at Ishioka station.  
3

4 A standard analysis approach for INT sessions was used:  
5

- 6 • All station coordinates were kept fixed on their a priori values, i.e. the IVS VTRF2019d (BKG 2019)  
7 values. For the OTT we used the corresponding VTRF2019d coordinates that were determined  
8 through dedicated short-baseline interferometry campaigns (Varenius and Haas 2020).  
9
- 10 • The radio source positions were kept fixed on their ICRF3 (Charlot et al 2020) values.  
11
- 12 • A priori information for the EOP was taken from *usno\_finals.erp* created 2020.08.19-23:00:17.  
13
- 14 • We fixed the clock for one of the stations as reference, while estimating 2nd order clock polynomials  
15 for the other stations involved.  
16
- 17 • We estimated one zenith wet delay parameter for each of the stations but atmospheric gradients were  
18 not estimated.  
19
- 20 • The UT1-UTC parameter was estimated.  
21

22 First, we investigated the agreement of the results of the two parallel baselines Is-Oe and Is-Ow by  
23 analyzing the two baselines individually and together. The short baseline Oe-Ow was excluded from any  
24 analysis due to the previously mentioned RFI problems. Figure 1 depicts the corrections to the a priori  
25 UT1-UTC from these three approaches. The results of all the analysis of the two individual baselines,  
26 i.e. Is-Oe and Is-Ow, agree within their formal errors. The analysis of both baselines together provides  
27 an average of the two result of the two individual baselines. With  $4 \mu s$  it also gives the lowest median  
28 formal uncertainty of UT1-UTC, while the median formal uncertainties for the individual baselines are  
29  $6 \mu s$  and  $5 \mu s$  for Is-Oe and Is-Ow, respectively. These formal uncertainties correspond well with the  
30 results from simulations performed with VieSched++. In the following we used the results of analysing  
31 both baselines together.  
32

33 Besides performing our own data analysis of the INT1 and INT2 sessions, we also downloaded the results  
34 of the corresponding analysis that were provided by five of the IVS Analysis Centres (IVS ACs). These  
35 were the Bundesamt für Kartographie und Geodäsie (BKG), the NASA Goddard Space Flight Center  
36 (GSF), the United States Naval Observatory (USNO), the Geospatial Information Authority of Japan  
37 (GSI), and the Institute of Applied Astronomy of the Russian Academy of Sciences (IAA). These IVS  
38 ACs routinely analyze the INT sessions and provide their results to the IERS for the determination  
39 of IERS rapid and final products (Luzum and Gambis 2014), IERS Bulletin A and IERS Bulletin B,

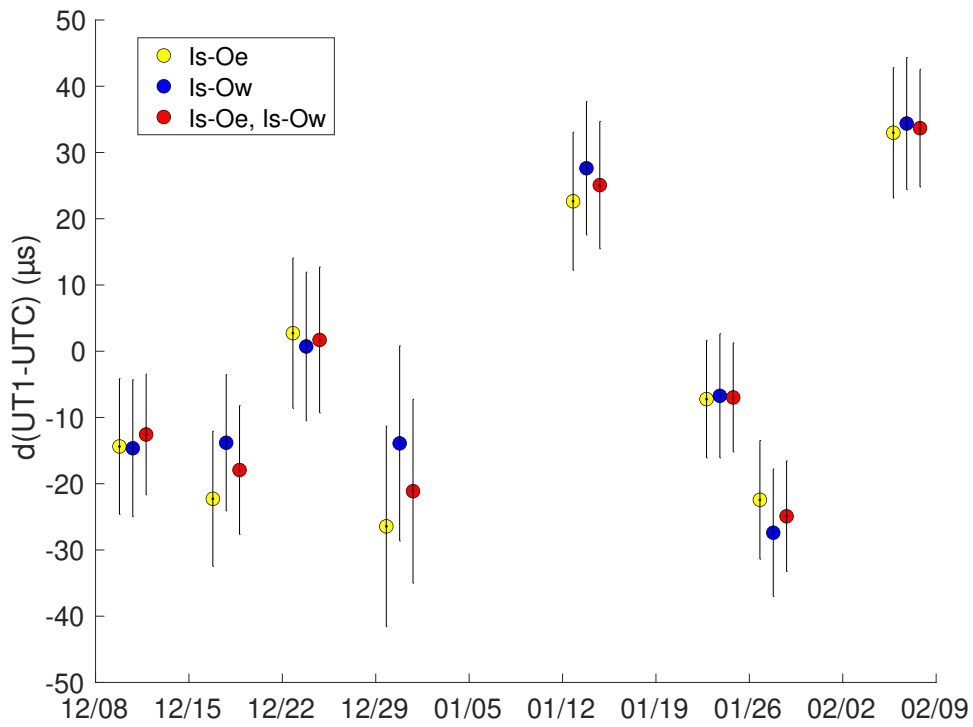

Figure 1. : Comparison of UT1-UTC corrections to the a priori values derived from analysing the VGOS-B baselines individually, i.e. Is-Oe (yellow) and Is-Ow (blue), and in a common analysis (red). The uncertainties shown are  $1\sigma$ .

1 respectively. All except GSI provide results for INT1 and INT2 sessions. The (few) results with formal  
2 uncertainties larger than  $100 \mu\text{s}$  were excluded from further comparisons.  
3

4 Figure 2 presents the UT1-UTC times series. The IERS Bulletin B values are shown as grey stars and  
5 the VGOS-B results as red circles. The INT1/INT2 results of the five IVS ACs are depicted in light blue  
6 as squares (BKG), upward-pointing triangles (GSF), downward-pointing triangles (USN), left-pointing  
7 triangles (GSI), and right-pointing triangles (IAA). Our own analysis results of the INT1/INT2 data are  
8 presented as light red diamonds. To increase the readability of this graph, all time series, except the  
9 VGOS-B one, are offset by  $-3 \text{ ms}$  each from the series shown directly above. The formal uncertainties  
10 of the presented results are on the order of a few  $\mu\text{s}$  to several tens of  $\mu\text{s}$  and thus not visible in this  
11 scale since UT1-UTC is changing a lot during the presented time interval. However, from a first glance  
12 at the graph it is obvious that all presented results show a similar signature and agree rather well. The  
13 VGOS-B results (red circles) do not show any obvious deviation with respect to the other data sets.  
14  
15

16 More insight is gained when investigating the differences between the individual UT1-UTC results and the  
17 IERS Bulletin B values. The latter are provided as daily values at epoch 00:00 UTC, while the INT1/INT2  
18 and VGOS-B results are given at the respective observation times of the corresponding session. Thus, to  
19 evaluate the agreement between the individual UT1-UTC series and IERS Bulletin B, the latter had to  
20 be interpolated to the epochs of the UT1-UTC series. For simplicity, and since all of the series do not  
21 include any high-frequent variations of UT1-UTC, we used a linear interpolation. Figure 3 depicts the  
22 times series of the resulting differences. It becomes clear that all series agree reasonably well with the  
23 IERS Bulletin B values, with maximum deviations well within the  $\pm 100 \mu\text{s}$  interval. Table 2 provides  
24 both the mean and median formal uncertainties of the individual series, their root mean square (RMS)  
25 agreement w.r.t. the IERS Bulletin B series, the biases, and the remaining scatter after removing the  
26 biases, expressed as standard deviation (STD). The VGOS-B data show both the smallest uncertainties,  
27 a small bias, as well as the best agreement in terms of RMS and STD. The improvements of the VGOS-B  
28 results w.r.t. to legacy S/X are between 30 % and 40 %, depending on which of the series compared with.

## 54 **Conclusions and outlook**

55 We scheduled, observed, correlated, post-correlation processed and analysed a number of VGOS sessions  
56 for the determination of UT1-UTC. These are the first sessions involving VGOS twin telescopes for  
57 this purpose. The involved VGOS stations were Ishioka (Is) in Japan and the Onsala twin telescopes

Figure 2. : Time series of UT1-UTC for December 2019 through mid February 2020. Shown are IERS Bulletin B values (grey stars) and the VGOS-B results as (red circles). The light blue symbols show the INT1/INT2 results of BKG (squares), GSF (upward-pointing triangles), USN (downward-pointing triangles), GSI (left-pointing triangles), and IAA (right-pointing triangles). The INT1/INT2 results from OSO are shown as light-red diamonds. To increase readability, all series, except the VGOS-B one, are offset by  $-3$  ms each from the series shown directly above.

Figure 3. : UT1-UTC differences w.r.t. to IERS Bulletin B for December 2019 through mid February 2020.

Table 2. : Statistics on the seven UT1-UTC times series. Shown are the mean formal uncertainties ( $\sigma_{\text{mean}}$ ), median formal uncertainties ( $\sigma_{\text{median}}$ ), the (unweighted) root-mean square agreement (RMS) w.r.t. the IERS Bulletin B series, the mean bias and the standard deviation (STD) after removing the bias. All values are given in unit  $\mu\text{s}$ . The relatively large uncertainty of the VGOS-B bias reflects the relatively few data points in this series.

Series	$\sigma_{\text{mean}}$	$\sigma_{\text{median}}$	RMS	bias	STD
BKG INT1/INT2	14	14	34	$18 \pm 4$	30
GSF INT1/INT2	16	13	28	$2 \pm 3$	28
USN INT1/INT2	16	13	30	$12 \pm 3$	28
GSI INT2	13	9	36	$14 \pm 7$	33
IAA INT1/INT2	14	13	29	$8 \pm 4$	28
OSO INT1/INT2	16	15	33	$13 \pm 4$	31
OSO VGOS-B	4	4	20	$-3 \pm 8$	20

1 (Oe, Ow) in Sweden, forming two parallel long east-west oriented baselines, i.e. Is-Oe and Is-Ow. We  
2 compared the derived UT1-UTC values from these VGOS-B sessions with corresponding results from  
3 our own analysis of INT1/INT2 data, the corresponding INT1/INT2 results of five other IVS ACs, and  
4 the final values of the IERS Bulletin B. The mean and median formal uncertainties of the VGOS-B  
5 derived UT1-UTC results are three to four times lower than the corresponding formal uncertainties of  
6 the INT1/INT2 results. This is in good agreement with simulations performed based on the actual  
7 schedules. The smallest formal uncertainties are achieved when analysing the two parallel baselines Is-Oe  
8 and Is-Ow together. The RMS agreement w.r.t. to IERS Bulletin B is better for the VGOS-B results  
9 than for the legacy S/X INT1/INT2 results and the VGOS-B results have a small bias only with the  
10 smallest remaining standard deviation. The RMS and STD improvements are on the order of 30-40 %.  
11 This improvement confirms the simulation study of Corbin and Haas (2019) where various scenarios of  
12 VGOS observations of UT1-UTC were investigated. Investigating six months of intensive observations  
13 by simulations, Corbin and Haas (2019) found an improvement of the UT1-UTC accuracy of more than  
14 40 % when simulating VGOS intensive sessions including one VGOS twin telescope station, compared  
15 to standard S/X legacy intensives. The good agreement of the VGOS-B results with IERS Bulletin B is  
16 also to some extent remarkable since the INT1/INT2 results provided by the operational IVS ACs are  
17 input data for the determination of the IERS Bulletin B, while the VGOS-B results are not. However,  
18 more VGOS-B sessions are necessary in order to verify this good agreement. The plan is thus to continue  
19 the VGOS-B sessions, starting in late November 2020, as soon as the Ishioka station is ready to observe  
20 VGOS again. With even more ( $\sim 100$ ) observations per baseline per hour, we expect these sessions to  
21 further improve the UT1-UTC determination. Finally, we note the possibility of Oe and Ow participating  
22 simultaneously in two different UT1-UTC sessions, a unique capability of the twin telescopes sites which  
23 can hopefully be investigated for upcoming VGOS intensive sessions.

#### 51 **Availability of data and materials**

52 The vgosDBs analysed in this study are publically available via the IVS webpages. The IERS Bulletin B  
53 results are available via the IERS webpages. The individual UT1-UTC series of the IVS ACS are available  
54 from the IVS.

## Funding

## Authors' contributions

RH, EV, SM and MS organised VGOS-B series, in coordination with the IVS Coordinating Center. MS scheduled the VGOS-B experiments. EV performed the VLBI data correlation and post-correlation analysis and created the final vgosDb. RH analysed the vgosDB with ASCoT and did the comparison analyses. All authors read and approved the final manuscript.

## Authors' information

## Acknowledgements

We acknowledge advice given by Mike Titus, Simone Bernhart, John Barret and Sergei Bolotin regarding correlation and post-processing of the VGOS B-sessions.

**UT1-UTC from legacy S/X and VGOS-B**

# Figures

**Figure 1**

Comparison of UT1-UTC corrections to the a priori values derived from analysing the VGOSB baselines individually, i.e. Is-Oe (yellow) and Is-Ow (blue), and in a common analysis (red). The uncertainties shown are  $1\sigma$ .

**Figure 2**

Time series of UT1-UTC for December 2019 through mid February 2020. Shown are IERS Bulletin B values (grey stars) and the VGOS-B results as (red circles). The light blue symbols show the INT1/INT2 results of BKG (squares), GSF (upward-pointing triangles), USN (downward-pointing triangles), GSI (left-pointing triangles), and IAA (right-pointing triangles). The INT1/INT2 results from OSO are shown as light-red diamonds. To increase readability, all series, except the VGOS-B one, are offset by -3 ms each from the series shown directly above.

**Figure 3**

UT1-UTC differences w.r.t. to IERS Bulletin B for December 2019 through mid February 2020.
