Abstract

Background: *Leishmania major* and *Leishmania tropica* cause cutaneous leishmaniasis in humans and dogs in several parts of the world, with a large number of cases recorded in the Middle East. However, when occurring in sympatry in the same area, the role of each species in the epidemiology of cutaneous leishmaniasis is not clear.

Methods: To determine the prevalence and to identify the species of *Leishmania* that infect humans and stray dogs in Riyadh and Al-Qaseem (Saudi Arabia), blood samples were collected from stray dogs (n = 311) and human patients (n = 27). A conventional PCR coupled with a nested PCR (n PCR) were applied in this study.

Results: A conventional PCR coupled with a nested PCR (n PCR) showed that seven patients (25.9%) from Riyadh city and Al-Qaseem province were infected by *L. major* and *L. tropica* and five dogs (1.6%) by *L. tropica*.

Conclusions: This is one of the first molecular studies of leishmaniasis from Saudi Arabia. The relationship between the sand fly vectors and the reservoirs of both *Leishmania* spp. is still scarcely known in this region, and further epidemiological investigations of domestic and wild canine infected with *L. major* and *L. tropica* are needed towards a control and prevention of the infection in canine and human populations.

1. Introductions

Leishmaniases are a complex of sand fly transmitted protozoa diseases, listed amongst the neglected tropical diseases affecting millions of people, mainly the world's most vulnerable populations [1]. These diseases are worldwide associated to the occurrence of phlebotomine sand flies of the genus *Phlebotomus* in the Old World and *Lutzomyia* in the New World. Leishmaniases include cutaneous (CL), visceral (VL) and mucocutaneous (ML) forms all of which have been reported in Saudi Arabia [2-4]. Moreover, in that Country CL by *Leishmania major* has the highest prevalence mainly in Riyadh, Qassim, Al-Madinah, Al-Hassa, Hail and Asir [5-7] with an estimated number of more than 26,300 cases [2] over the past 10 years (2006–2016). In addition, in Saudi Arabia there are several reports of leishmaniasis by *Leishmania infantum*, *Leishmania arabica*, *Leishmania major* and *Leishmania tropica* among dogs and humans [8-12]. In spite of the number of molecular studies available to diagnose and identify *Leishmania* species worldwide [13-16] there is a lack of information on CL in human and dog populations from endemic areas of Saudi Arabia [17, 18]. Therefore, the aims of the current study were to detect and identify the *Leishmania* species infecting humans and stray dogs in Al-Qaseem province and Riyadh city, Saudi Arabia in order to better understand the epidemiology of the infection.

2. Materials And Methods

2.1 Ethical approval

This study was reviewed and approved by the Ethics Committee of the Department of Biological Science at Shaqra University, according to the ethical principles of animal research (protocol SH 2-2017).

2.2 Study areas

The investigation was conducted from January 2018 to May 2019 in Al-Qaseem province and Riyadh city, Saudi Arabia. Al-Qaseem province is located at the central part of Saudi Arabia (latitude 25°–23° N and longitude 42°–24° E). It has an area of about 58.046 km² and was reported to be inhabited by approximately 1,423,000 people in 2017 (General Authority for Statistic, 2017). Riyadh city is the capital of Saudi Arabia (latitude 24°–08° N and longitude 47°–18° E), with an area of about 1798 km² and inhabited by approximately seven million people in 2016 [19] (**Figure 1**).

2.3 Patients Biopsy tissue collections and gDNA extraction

A total of 27 suspected patients were attended in King Saud Medical City in Riyadh city (n =16) and Buraidah Central Hospital (n =11) in Al-Qaseem province. All samples were diagnosed after clinical and microscopy examination [20]. Briefly, skin biopsies (i.e., 5-10 mm of diameter) were taken under sterile conditions from the border of the ulcer and cutaneous lesions and DNA samples were extracted from all biopsies by MagNaA pure DNA extraction Pure LC DNA Isolation Kit (Roche Applied Science, Mannheim, Germany) according to the manufacturer's instruction (Roche) and the extracted gDNA was checked by Nanodrop spectrophotometer (Thermo, USA), and an aliquot (100 µl of gDNA from each sample) stored at -20 °C prior to nPCR amplification and analysis.

2.4 Sampling of stray dogs

From January 2018 to May 2019, 311 stray dogs were trapped in Al-Qaseem province by bait traps (Havahart®), dogs examined physically for CL in the field and a blood sample of 2-5 ml from the cephalic vein into EDTA vacuum tubes (BD Vacutainer® Tube, Gibbles Pathology, VIC, Australia) and transported to the molecular laboratory, Shaqra University for DNA extraction and further molecular analysis. Seven of the above animals were suspected for CL due to the presence of cutaneous nodules or ulcerated lesions on the skin. Skin biopsies (5 mm in diameter) were taken under sterile conditions from the border of the ulcer and inoculated into medium M199 supplemented (Gibco, Life technologies, Germany) with 25 mmol/L HEPES (pH:7.5) and 20% fetal bovine serum (Gibco, Life technologies, Germany) followed by incubation at 24 °C. Ten days later parasites were harvested and washed with ice-cold phosphate buffered saline (PBS, pH: 7.4) and stored in -20 °C before DNA isolation.

2.5 Leishmania Nested PCR (nPCR)

The specific external CSB2XF primers (5'-ATTTTTCGCGATTTTCGCAGAAACG-3') and CSB1XR (5'-CGAGTAGCAGAACTCCCGTTCA-3') were used initially. In the second step, specific internal 13Z primers (5'-ACTGGGGGTTGGTGTAATAAG-3') and LiR (5'-TCGCAGAACGCCCT-3') were applied [21]. These primers were able to track the variable part of all forms of the Leishmania kDNA minicircle [21]. The first

step of PCR master mix that included CSB2XF and CSB1XR were applied using AccuPower® PCR PreMix kit (Bioneer, Daejeon, Korea). The prepared PCR premix volumes contained KCl 30 mM, MgCl₂ 1.5mM, Tris-HCL (pH 9.0) 10mM, Taq DNA polymerase, and dNTP were adjusted to 2 µl. In addition, 1 µl of the first step of each initial CSB1XR and CSB2XF primers at concentrations of 10 pmol (Bioneer, Daejeon, Korea) and 3 µl of genomic DNA were added to the complex. Finally, 13 µl of deionized water (ddH₂O) were added for a total volume of 20 µl for reaction. The reaction was performed in a thermal cycler (Techne TC-3000, USA) by set up the following conditions; initial denaturation temperature of 94 °C for 5 min; followed by 30 cycles at denaturation 94 °C for 30 s, annealing 55 °C for 60 s, extension 72 °C for 60 s, final extension at 72 °C for 7 min and then the reaction was held at 4 °C. The second step of PCR included 13Z and LiR primers and the same PCR master mix except 3µL of template PCR product. After that, PCR products were electrophoresed on a 1.5% agarose gel containing 1 µL/mL Syber safe (Thermo Scientific™, Nalgene, UK) in Tris-acetate–EDTA buffer at 100 V for 45 min and visualized under UV imaging system (ImageQuant Laz4000, GE Healthcare Life Science, Hammersmith, UK). The size of each sample was estimated by comparison with a 100 bp DNA Ladder Marker (Solis BioDyne OU, Estonia).

2.6 Leishmania kDNA sequencing and phylogenetic analysis

Positive amplified products of Leishmania species were sent to **Macrogen (South Korea)** for sequencing, and the results were compared with the sequences available in GenBank database using BLAST (<http://blast.ncbi.nlm.nih.gov/>). The phylogenetic analysis was performed based on NCBI-Blast alignment identification and maximum composite Likelihood method by phylogenetic tree UPGMA method (MEGA 7.0 version). Bootstrap values were determined with 1,000 replicates of the data sets [22]. The sequences will be deposited onto GenBank (AN will be provided in the R1).

3. Results

Of the 27 human patients examined five from Riyadh and two from Al-Qaseem were positive to *L. major* and *L. tropica* respectively (**Figure 2 and 3**). Of 311 dogs, seven (2.3%) presented with thick cutaneous lesions (i.e., 1.5 × 5 centimeters) in different anatomical sites (e.g., nose, muzzle, abdomen and between fingers) and five of them were positive to *L. tropica*. Sequencing analysis of *Leishmania* kDNA confirmed that the five positive samples (nos. H1-H5) of the human patients from Riyadh were all *L. major* with a size ranging from about 441 bp to 451 bp yielding a nucleotide identity ranging from 99.34% to 99.56 % with previous *L. major* sequences from Iran (AN LC036307.1). *Leishmania* sequences from two human patients (nos. H1 and H3) from Al-Qaseem were identical to *L. tropica* from Iran (AN AB678350.1) (**Figure 4 and Table 1**). Sequences of *Leishmania* kDNA from stray dogs (no. D2, D4 and D7) were closely related (i.e., 99.33% to 99.5%) to kDNA of *L. tropica* from Iraq (MF166799.1), whereas two sequences (no. D5 and D6) displayed a close nucleotide identity (i.e., 99.55%) to *L. tropica* kDNA from Iraq (AN MF166800.1; **Figure 4 and Table 1**). Phylogenetic tree clustered *L. major* (no. H1-H5) and *L. tropica* (no H1 and H3) sequences from human samples to those from Iran (accession number LC036307.1 and AB678350.1, respectively), and the phylogenetic tree clustered *L. tropica* (no. D2, D4 and D7) and (no. D5 and D6)

sequences from dog's samples to those from Iraq (accession number MF166799.1 and MF166800.1, respectively; **Figure 4**).

4. Discussion

This study provides molecular evidence of the circulation of *L. major* and *L. tropica* in human and dog populations from the investigated areas. The above *Leishmania* spp. have already been recorded as agents of cutaneous leishmaniases in Saudi Arabia and Middle Eastern countries [23-26]. However, *L. tropica* infection has been herein molecularly diagnosed for the first time in humans and dogs in the central part of the Saudi Arabia since it was previously reported in the west and southern west of Saudi Arabia in association with the distribution of the sand fly species (i.e., *Phlebotomus sergenti*), which is a proper vector for that species [27]. Conversely, *L. major* is more prevalent throughout the Country and can be found in the open deserts regions of Saudi Arabia [2, 28]. Previous studies in Saudi Arabia have reported the natural infection of *L. major* in dogs using enzymatic biochemical methods [29, 30], though no clinical information was available, nor serology or molecular confirmation were performed. The high nucleotide identity of human *L. major* and *L. tropica* isolates with those of Iran (accession number AB678350.1 and LC036307.1) as well as of dog *L. tropica* isolates with Iraq (accession number MF166799.1 and MF166800.1) was also confirmed by the phylogenetic dendrogram herein presented. This might be due to the distribution of similar sand flies species in the Middle East, which may act as proper vectors of both *Leishmania* spp. [24, 31].

Of the 25 species of *Phlebotomus* reported in Saudi Arabia only five (i.e., *Phlebotomus papatasi*, *P. sergenti*, *Phlebotomus bergeroti*, *Phlebotomus kazeruni*, and *Phlebotomus arabicus*) have been incriminated as vectors of CL [27, 28, 32, 33]. Of these, *P. papatasi* is the major and most predominant vector species for *L. major* [28, 32], while *P. sergenti* is the natural vector species for *L. tropica* [27]. Presence of *P. papatasi* and *P. sergenti* in Al-Qaseem province suggests that they could have a potential role in the transmission of human and canine leishmaniasis. Nonetheless, still more studies are required to elucidate the role of *Phlebotomus* spp. in CL disease transmission in Saudi Arabia.

Stray dogs have been often diagnosed in Saudi Arabia, with clinical disease associated with *Leishmania* species, however previous studies focused on the epidemiology, clinical, histopathological and biochemical aspects [11, 29, 30]. Conversely, molecular studies have reported the occurrence of dog infection by *Leishmania* spp. in Qatar [34], *L. tropica* in Iran [26, 35] and Israel [36, 37] and by *L. major* in Iraq [23] and Israel [25], which are in agreement with the current study. Though CL is endemic in many parts of Saudi Arabia, the paucity of data concerning the relationship between the disease, the vectors and reservoirs is a major hindrance to understand the transmission cycles in endemic areas. Data herein provided contribute to fill existing gaps in order to increase the alert by the Ministry of Health in Saudi Arabia in preventing outbreaks and the spread of CL.

5. Conclusion

This is one of the first molecular epidemiological studies that detected and identified CL in stray dogs and patients from Saudi Arabia thus confirming that *L. major* and *L. tropica* are endemic in Al-Qaseem province and Riyadh City. However, it is still unclear the relationship between the sand fly vectors and reservoirs and their specific role in the transmission cycles in endemic areas of Saudi Arabia. More epidemiological and molecular studies

Declarations

Ethics approval and consent to participate

Blood and tissue sampling for this study was approved by the Ethical Research Committee, Shaqra University and complied with relevant guidelines for animal handling and welfare. (Approval no. SH 02-2017)

This project was kindly supported by Shaqra University and King Abdulaziz city for Science and Technology (KACST), Saudi Arabia. The authors would like to thank the Staff Members of the Biological Sciences Department, Faculty of Science and Humanities, Shaqra University for kind technical support.

Authors' contributions

ADA, ASA and AAR conceived the study. MSA, ASA performed field works. ASA collected patient's and dog's samples. ASA, AAR and MAA carried out the biopsy tissue collections and DNA extraction. MAA, AAR and FAR performed laboratory works and analyzed data. ADA, MSA and FAR wrote the first draft of the manuscript. JM-R, DO, RD and ADA reviewed and wrote the final draft of the manuscript. All authors read and approved the final manuscript.
