Abstract

Background: U-box gene is gene of ubiquitin ligase, which contain U-box domain. Plant U-box gene (PUB) plays an important role in the response to stresses, but less reports about PUBs in cotton were issued. Therefore research of PUBs in cotton will be of great importance and necessity to study the mechanism of tolerance-resistance of the cotton. Results: In this study, we identified 93, 96, 185 and 208 PUBs from the three sequenced cotton species *G. raimondii* (D5), *G. arboreum* (A2), *G. hirsutum* (AD1) and *G. arbadense* (AD2), respectively. Subcellular localization analysis showed that the PUBs in cotton were distributed in various parts of the cells, mainly in the nucleus. The PUBs in cotton were divided into six subfamilies (A-F) by phylogenetic analysis, and intron/exon structure was comparatively conserved within the subfamily. Location analysis showed cotton PUBs were unevenly anchored on all the chromosomes varying from 1 to 14. It was found that there are 3 tandem duplications and 28 segmental duplications in cotton genome D5, 2 tandem duplications and 25 segmental duplications in A2, and 143 homologous gene pairs between A2 and D5, through multiple sequence alignment, but that the tandem duplication region of A2 or D5 was not found. It was also found that, there were 105, 14 and 17 homologous gene pairs in intra-subgenome of At and Dt, At subgenome, Dt subgenome of allotetraploid cotton, respectively. Among the PUBs family, totally 106, 116, 85 and 81 homologous gene pairs were found in A2-At, A2-Dt, D5-At and D5-Dt. Function analysis of GhPUB85A and GhPUB45D showed they positively responded the abiotic stresses, but the expression patterns were different. Besides, although the expressions of these two homologous genes were similar, their contributions were different when responding to stresses, showing different response differences to abiotic stresses and function division of two subgenomes of *G. hirsutum*. Conclusion: This study provided the genome-wide identification, structure, evolution and expression analysis of PUBs in cotton, and the results showed that the PUBs was highly conserved in evolutionary history of cotton. All PUB genes were involved in response to abiotic stresses at varying degrees.

Background

The ubiquitin-mediated ubiquitination pathway is the post-translational modification pathway of eukaryotic proteins. Studies demonstrated that the pathway is involved in cell cycles in higher plants [1], stress resistance [2], signal transduction [3], apoptosis [4], optical signal [5] and other physiological pathways. In ubiquitin pathway, it takes three steps for the ubiquitin to act on the target protein. First, the ubiquitin-activating enzyme (E1) activates ubiquitin [1], and then the activated Ub molecules and delivered to the ubiquitin-binding enzyme (E2) [2]; finally, Ub molecules are transferred to the target protein through ubiquitin ligase (E3). E3 is responsible for identification of the specificity of substrate protein, and has the most species [3]. In Arabidopsis, there are more than 1,400 genes encoding components of the ubiquitination pathway, of which about 90% the encode ubiquitin ligase E3 [3, 4]. According to its subunit composition and mechanism of action, the ubiquitin ligase E3 can be divided into single subunit type (such as HECT, RING/U-box) [5] and multi-subunit type (such as SCF (skp1-cullin-F-box), APC (anaphase-promoting complex) [6], VBC (VHL-elongin B-Elongin C), *etc.*) [7, 8].

PUBs were reported in many model crops including *Arabidopsis*, rice, *Chlamydomonas reinhardtii*, Chinese cabbage, and soybean. Previous studies showed 64 *PUBs* were identified in *Arabidopsis* [9], 77 in rice [10], 33 in *Chlamydomonas reinhardtii* [11], 101 in Chinese cabbage [12] and 125 in the soybean [13], indicating that *PUB* genes exist widely in plants and plays an important role in plants. Many studies have shown that *PUB* proteins were involved in abiotic stress responses. Cho et al. [14] obtained U-box E3 protein (CaPUB1) from the drought-treated pepper. In *Arabidopsis*, the heterologous overexpression of *CaPUB1* attenuated the tolerance of plants to drought stress, two homologous proteins AtPUB22 and AtPUB23 in *Arabidopsis* were also involved in the drought stress response of plants [15]. Furthermore, studies also showed that AtPUB22 and AtPUB23 could modulate negatively the drought stress response of plants by synergistic ubiquitination of RPN12a [15]. Liu *et al.* identified a U-box E3 protein AtPUB19 induced by drought, high salt, cold and ABA. *atpub 19* mutant plants promoted stomatal closure, thereby enhanced tolerance to drought of the plants; *AtPUB19*-overexpressing plants are not sensitive to ABA but sensitive to drought. Meanwhile, there are significant changes in expression levels of ABA and stress-related genes in *atpub 19* mutant and *AtPUB19*-overexpressing plants, indicating AtPUB19 may regulate the drought stress by negative regulation of ABA signal [16]. *PUB* proteins, involved in the process of drought response, were also identified in rice. Previous studies showed drought resistance of *OsPUB15*-overexpressing plants significantly enhanced, and *OsPUB15* could be induced by hydrogen peroxide, drought and high salt, indicating that *OsPUB15* may positively regulate the response of plants to drought stress by attenuating intracellular oxidative stress [17].

Cotton is the most important fiber crop and the model crop for the research of polyploidy, evolution, cell wall development, and cellulose synthesis [18]. There were approximately 50 species distributed in arid and semi-arid regions of the tropic and subtropics, which were presumed to have originated from the same ancestor 50 to 100 million years ago [19]. The current cultivars are diploid *G. arboreum* and *G. herbaceum*, tetraploid *G. hirsutum* and *G. barbadense*. The tetraploid cottons originate from hybridization between the African ancestral species of A genome and the American ancestor species of D genome one to two million years ago [18]. Recently the completed sequencing work of diploid cottons (*G. raimondii* (D5) [20, 21], *G. arboreum* (A2) [22] and allotetraploid cottons (*G. hirsutum*TM-1 (AD1) [23, 24], *G. barbadense* acc.3-79 (AD2) [25] provided the reference for the study of gene function and evolution from the whole genome level. Based on the cotton genome sequences, the family members of *PUB* gene were identified and the structure and distribution characteristics of *PUB* gene were analyzed, as well as its evolution analysis in whole genome replication and cotton allotetraploid formation.

Materials And Methods

Cotton and *Arabidopsis thaliana*

Upland cotton variety ZhongS9612 was selected and preserved by the Cotton Adversity Research Laboratory at the Chinese Academy of Agricultural Sciences (CAAS) for many years. Before planting into the sand, the seeds were surface-sterilized with 0.1% HgCl₂ and placed in a sterile dish with moist filter paper to accelerate germination. Uniform seedlings were chosen and transplanted into sand pots (10

plants in each pot) in the greenhouse (14 h/day, 30°C and 10 h/night, 24°C) at the Institute of Cotton Research of CAAS. For the agrobacterium-mediated transformation, we referred the method used by Lu et al [26].

Whole genome identification of *PUBs* in cotton

Cotton genome data (*G. raimondii* (D5) [20, 21], *G. arboreum* (A2) [22], *G. hirsutum* acc. TM-1 (AD1) [23, 24]) were obtained from CottonGene (<https://www.cottongen.org/>). Hidden Markov Model (HMM) profile of U-box domain (PF04564) was obtained from Pfam30.0 (<http://pfam.xfam.org/>) [27], and was used as a query to identify the candidate PUBs from the cotton genome protein database using HMMER3.0 [28]. We used BLAST2.2.31+ (<ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/LATEST/>) to get coding domain sequence (CDS) sequences, protein sequences and the corresponding entire sequence on the genome. The protein sequences were further analyzed in SMART (<http://smart.embl-heidelberg.de/>) and Pfam 30.0 [27] database to ensure each candidate protein contains U-box domain. Subcellular localization prediction was carried out in CELLO v.2.5 [29].

Exon-intron structure, phylogenetic and conservative domain analysis

The identified CDS sequence and the genome sequence of cotton *PUBs* were used to analyze *PUBs* structure by GSDS2.0 [30]. The full-length sequences of PUB proteins were used to construct phylogenetic tree. Multi-sequence alignment of PUBs was carried out by ClustalX1.83, and Neighbor-Joining (NJ) method [31] was used to construct phylogenetic tree in MEGA6.0 [32]. The online software SMART, PROSITE [33] were used to analyze the conserved domains of protein.

Physical location of *PUBs* in cotton

GFF (general feature format) files of cotton *PUBs* were obtained from the genome annotation files, and the information on *PUBs* of chromosome position was projected from it. The distribution of cotton *PUBs* on the chromosome was drawn with MapInspect (<http://mapinspect.software.informer.com/>).

Gene duplication and microsynteny analysis among *G. arboreum*, *G. raimondii* and *G. hirsutum*

Homologous gene pairs were identified according to multiple sequence alignment results and the standard described in previous studies [34, 35]. The collinearity of homologous genes was drawn in Circos [36] based on the homology between them and their positions on the genome.

Gene cloning and the construction of vectors

The first strand was synthesized according to the instructions of TransScript one-step gDNA removal and cDNA synthesis supermix kit. Two homologous genes GhPUB85A and GhPUB45D were cloned using In-fusion technology. Primers were designed on the website and sequences were below: InGhPUB85A-V-Foward 5'-TAAGGTTACCGAATTCATGGTTGAAAGTGGAAAG; InGhPUB85A-V-Revers 5'-TCGGGACATGCCCGGGTTTCACAAGCCTCCTTC; InGhPUB45D-V-Foward 5'-TAAGGTTACCGAATTCCTTGGTTGAAAGTGGAAAG; InGhPUB45D-V-Reverse 5'-

TCGGGACATGCCCGGGCTTCACAAGCCTCCTTC. PCR amplification products were verified using 1.5% agarose gel electrophoresis. PCR amplification products were purified using MiniBEST Agarose Gel DNA Extraction Kit from Takara Corporation. Finally the concentration of targets were measured, and stored at -20°C for use.

Targets purified were linked to pEASY-Blunt Cloning Vector, and then transformed into *Escherichia coli* according to the instructions of pEASY-Blunt Cloning Kit. Positive clones were selected and inoculated into LB liquid medium containing Kana (0 mg•L⁻¹) for about 6h under the conditions of 200 rpm and 37 °C. Then the positive clones were verified using PCR amplification with M13 primers. Finally clone vectors GhPUB85A-t and GhPUB45D-t were obtained. PCR reaction system used in the research was below: 5×PrimerSTAR GXL Buffer, 10 µl; dNTP Mixture (2.5 mM each), 4 µl; F-primer (10µM), 1.5 µl; R-primer (10µM), 1.5 µl; cDNA, 100 ng; 5×PrimerSTAR GXL DNA Polymerase, 100 ng, 5×PrimerSTAR GXL DNA Polymerase, 2 µl; add ddH₂O to 50µl. PCR procedure of gene amplification used in the research was: 98 °C, 10s; 55 °C, 15s; 68 °C, 9s; 4°C, forever, 35cycles. Real-time PCR method was used to measure the relative expression of two genes. Primers of two genes used were below: qGhPUB85A-Foward: ATGGTTGAAAGTGAAG; qGhPUB85A-Reverse: TTTCACAAGCCTCCTTC; qGhPUB45D-Foward: TTGGTTGAAAGTGAAG; qGhPUB45D-Reverse: CTTACAAGCCTCCTTC. GhHistone3 (AF02471) was used as the reference gene.

VIGS analysis of GhPUB85A and GhPUB45D

Based on vector sequence, target gene sequence and enzyme cutting sites, In-fusion primers were designed on the website (<http://bioinfo.clontech.com/infusion>). Primer sequences of InGhPUB85A-V and InGhPUB45D-V were shown before. Primer sequences of GhPUBs-RFP and InGhPUBs were below: GhPUBs-RFP-Forward: CACGGGGGACTCTAGAATGGTGTGAGGTTGCGGCATTA; GhPUBs-RFP-Reverse: AGGAGGCCATCCCGGGGTCCAATTTGTAAGCCCAACC; InGhPUBs-Forward: CTCTAGAGGATCCCGGGGATGGTGTGAGGTTGCGGCATT; InGhPUBs-Reverse: GATCGGGGAAATTCGAGCTCTTAGTCCAATTTGTAAGCCCA. Finally silencing vectors pYL156:GhPUB85A and pYL156:GhPUB45D, and RFP vectors pBI121-GhPUB85A:RFP and pBI121-GhPUB45D:RFP, and Plant overexpression vectors pBI121:GhPUB85A and pBI121:GhPUB45D were totally constructed. All vectors were transformed into cotton and *Arabidopsis thaliana* with agrobacterium mediated genetic transformation method.

Results

Identification of PUB gene family members in whole genome of cotton

The hidden Markov model (HMM) of U-box domain (PF04564) was downloaded from the database Pfam30.0, and used as a query to identify the candidate PUB members in four cotton genomic database using HMMER3.0. SMART. Besides, Pfam30.0 was also used for further identification to confirm every PUB members containing U-box domain. Finally, 93, 96, 185, 208 *PUBs* were identified from the four

sequenced cotton species, *G. raimondii* (D5), *G. arboreum* (A2), *G. hirsutum* acc. TM-1 (AD1), and *G. barbadense* (AD2), respectively, which were named *GrPUB1-93*, *GaPUB1-96*, *GhPUB1A-89A/1D-91D/181-185* and *GbPUB1A-98A/1D-98D/197-208* according to their location on the chromosome. The gene number of tetraploid cottons was the twice as many as that in diploid cottons, showing *PUB* genes are relatively conservative. The information about gene name, locations, length of open reading frame (ORF), type of protein domain, position of U-box domain and subcellular localizations of these gene family members could be found (**Supplementary Table S1, Supplementary Table S2, Supplementary Table S3**). The length of the *PUB* protein sequence in cotton ranges from 49 to 1492 AA, and the U-box domain contains about 75 amino acids. However, the length of U-box domain was almost the same except a few *PUBs*, for example, *GaPUB39* and *GhPUB40D* has only 32 and 50 amino acids, respectively. Subcellular localization analysis showed *PUB* proteins distributed throughout the cell, including nuclear, cytoplasmic, chloroplast, Plasma Membrane, mitochondrial, and extracellular. But most *PUB* proteins are located in the nucleus. 20 different domains were found in all cotton *PUBs* (**Table 1**), and the primary mode was “U-box+ARM/HEAT”. Different domain modes may be associated with different functions of cotton *PUBs*.

Analysis of *PUBs* gene structure and evolution in cotton

Gene structure diagram of *PUBs* and evolution tree were constructed (**Supplemental Figure S1, Supplemental Figure S2, Supplemental Figure S3 and Supplemental Figure S4**). Based on the evolutionary relationship, the *PUB* genes could be divided into five subgroups (I-V). Among these subgroups, subgroup I was composed of domains “U-box + ARM” and “U-box only”, and the rest subgroups were composed of other domains. The exon number of *PUB* genes in cotton is greatly divergent, ranging from 1 to 25. Among all the *PUBs*, approximately 1/3 *PUBs* contain only one exon. Generally, the evolutionary relationship is somehow correlated with gene structure, that is, the more similar the number and size of the exon, the closer evolutionary relationship. In *G. hirsutum*, the length of *GhPUB1A* is 47Kb, much larger than other *PUB* genes, which may be correlated with the assembly and annotation of the cotton genome. Members in each subgroup in *G. barbadense* (AD2) was greatly different with that in *G. raimondii* (D5), *G. arboreum* (A2) and *G. hirsutum* (AD1), which may be correlated with the different origins of these species. So the evolution of *PUBs* in *G. raimondii* (D5), *G. arboreum* (A2) and *G. hirsutum* (AD1) was analyzed, and the results also indicated 4 subgroups were found (**Supplemental Figure S5**), and this was similar with the evolution of single *PUB* gene, suggesting the *PUB* members were highly conservative. Furthermore, more close evolution relationships of *GhPUB1A-89A* with *GaPUB1-96* and *GhPUB1D-91D* with *GaPUB1-93* were found based on the evolution analysis.

Location of *PUB* Genes in three cotton genomes

The MapInspect software was used to draw the distribution map of *PUB* genes on the chromosomes based on the position information. Among 93 genes in *G. raimondii*, 91 were located unevenly on the chromosome and others were found on Scaffolds (**Figure 1A**). The results indicated that only a few genes were found on chromosome 3, 4, and 12, and the *PUB* genes on chromosome 5 were the most (11 *PUBs*). Besides, *PUB* genes on chromosome 4, 6, 7, 11 and 12 were biasedly enriched towards one end of the chromosome. All of 96 *PUB* genes identified in *G. arboreum* were located on different chromosomes (**Figure 1B**). The results showed uneven distribution of *PUBs* on each chromosome in *G. arboreum*, and

chromosome 1 enriched the most PUB genes (up to 14) and chromosome 3 enriched the least PUB genes (only 2). Besides, the length of chromosome 5 was about 6 Mb, but there were 9 PUB genes were found, showing the highest distribution density. In *G. hirsutum*, 91.4% (169/185) PUB genes were anchored on chromosomes, among of which 82 and 87 genes were found A- and D- subgenome, respectively (**Figure 2**). The number of PUB genes on chromosome 7 was the most and chromosome 8 was the least compared with other chromosomes in both At- and Dt- subgenome in *G. hirsutum*, showing PUBs on these two chromosomes were relatively conservative and significant for cotton growth. The situation in *G. barbadense* was different with *G. hirsutum* (**Supplemental Figure S6**). The results showed PUB gene were equally distributed in At- and Dt- subgenome and unevenly located on each chromosome, which may be correlated with differentiation of two species.

Gene duplication analysis

Fragment duplication of the chromosomal region may result in the scattering of the gene family members on multiple chromosomes. Compared with other eukaryotes, plants always have a higher rate of gene replication. Recent studies have shown that *G. raimondii* have had at least two complete genome-wide replicates [30]. Segregation of cotton A genome and D genome diploid occurred in about 5-10Myr years ago [18], and allotetraploid *G. hirsutum* was generated from hybridization of diploid cottons and the number of chromosomes were doubled 1-2Myr years ago. In the study, BLAST2.2.31+ (<ftp://ftp.ncbi.nlm.nih.gov/blast/executables/blast+/LATEST/>.) was used for blastn and blastp (value 10) screening of homologous gene pairs from the cotton *PUB* genes identified. The uneven distribution of genes on the chromosome may be the result of gene duplication or partial fragment replication during the long evolutionary history of the cotton genome. Each time the replication occurs, the entire genetic sequence of cotton is doubled, and over time, these redundant genes are recombined or lost [23]. Previous studies have shown that gene duplication and post-segregation phenomena are two major driving forces of evolution [32]. Based on the multiple sequence alignment of the encoding sequences and proteins in diploid cotton, 18 and 27 homologous gene-pairs were discovered with MCScanX [37] in *G. raimondii* (D5) (**Supplemental Figure S7A**) and *G. arboreum* (A2) (**Supplemental Figure S7B**), respectively. Among these homologous gene-pairs, 15 segmental duplications and 3 tandem duplications were found in *G. raimondii*, and 25 segmental duplications and 2 tandem duplications were found in *G. arboreum*. The relationship between two diploid cottons and *G. hirsutum* was analyzed (**Supplemental Figure S8**). Totally 197 homologous gene-pairs were found between *G. raimondii* and *G. hirsutum*, among of which 58.89% (116/197) were located on Dt-subgenome, and 191 homologous gene-pairs were found between *G. arboreum* and *G. hirsutum*, among of which 55.50%(106/191) were located on At-subgenome. All these results showed more than half of homologous genes in *G. hirsutum* were derived from corresponding diploid cotton genome. Furthermore, approximately 41.11% - 44.50% homologous genes were originated crosswise from other diploid genome.

Expression pattern analysis of PUB genes in cotton

Based on previous transcriptome data of PUBs under different stresses (salt, drought, low temperature and high temperature) in *G. hirsutum*, 117, 148 and 119 PUB genes were found with FPKM >1 in root,

stem and leaf, respectively, displaying tissue specificity. Among all the PUB genes, approximately 21 PUB genes with no expression were identified in three tissues, which may be associated with other specific regulations. Interestingly, it was found that 3 PUB genes (including GhPUB58D, GhPUB55A and GhPUB67D) always highly expressed in three tissues under salt, drought, low temperature and high temperature stresses. All PUB genes were divided into five subgroups (I, II, III, IV and V), similar expression patterns were found among all PUB genes (**Supplemental Figure S9 and S10**). In subgroup I, 18 PUB genes with huge expression difference were discovered, otherwise, other PUB genes in subgroup II-IV were found to have a consistent expression pattern under different stresses. But 4 PUB genes (*GhPUB32A-GhPUB38D*) in subgroup V were found with little expression difference under different stresses.

Cloning and function analysis of GhPUB85A and GhPUB45D

The evolution relationship in supplemental figure S5 showed *GhPUB68A*, *GhPUB85A*, *GhPUB45D* and *GhPUB69D* were belonged to subgroup I, showing their close relationship between each other. The transcriptome data showed *GhPUB85A* and *GhPUB45D* were highly expressed whereas *GhPUB68A* and *GhPUB69D* were almost not expressed at all. In order to investigate the response to stresses of homologous genes in cotton, qRT-PCR was used to study the expression difference in *G. hirsutum* TM-1. Drought, salt and low-temperature treatments were conducted and the results could be found in **Figure 3**. Higher expression of *GhPUB85A* and *GhPUB45D* under three stresses suggested they were actively expressed to respond the abiotic stresses, but *GhPUB68A* and *GhPUB69D* were not. In the research, interestingly, the highest expressions of *GhPUB85A* and *GhPUB45D* were found at 6h under drought stress, but the expressions at 12h were the highest under salt and low-temperature stress, indicating *GhPUB85A* and *GhPUB45D* responded to drought stress faster than salt and low-temperature stress. However, significantly different expressions of two genes under the same stress were, showed their different contributions in responding to abiotic stresses.

Based on the gene expression, *GhPUB85A* and *GhPUB45D* were cloned using cDNA from *G. hirsutum* TM-1 as template, and connected to pEASY-Blunt Cloning Vector for sequencing. The sequencing and enzyme digestion results showed the length of targets were correct. Red fluorescence vectors pBI121-GhPUB85A:RFP and pBI121-GhPUB45D:RFP were constructed to research their subcellular localizations (**Figure 4**), and the results showed these two genes were located at cytomembrane, which were consistent with our prediction. Besides, two VIGS vectors pYL156:GhPUB85A and pYL156:GhPUB45D were constructed using In-Fusion technology to study their functions under different stresses. 15d after the VIGS infection, the leaves of the positive control plants were obviously albino, and all the new leaves were albino in the later stage, while the others were normal (**Figure 5a**). Huge relative expression changes of two targets after the VIGS infection under different treatments showed their positive functions in responding multiple stresses and the success of VIGS infection (**Figure 5b-d**), which also suggested the VIGS infection technology was an effective way to study the gene functions in cotton.

Discussion

PUB gene family has been identified and analyzed in a number of plants [10, 12-14]. In the study, bioinformatics analysis was performed on allotetraploid cotton genome AD1 and diploid cotton genomes A2 and D5, and finally a total of 374 *PUB* genes were identified, including 185 in genome AD1, 96 in genome A2, and 93 in genome D5, indicating that it is a relatively conservative family in cotton genome evolution. Whole-genome replication analysis revealed that the ancestors of *G. arboreum* and *G. raimondii* had gone through a cotton-specific genome-wide replication event that occurred about 1.6 million years ago after differentiation with cocoa about 33 million years ago [33]. Recent studies have shown that *G. raimondii* have had gone through at least two complete genome-wide replicates [24, 38], resulting in an uneven distribution of the *PUB* genes on the chromosome, and over time, some genes are reassembled or lost. The results also showed that 19 out of 96 *PUB* genes in *G. arboreum* were generated through tandem repeats, which was one of the main reasons for the expansion of this gene family.

The classification of *PUB* protein differs from that of other gene families - it depends not only on U-box homology but on other domains other than U-box [39]. The evolutionary relationship of *PUB* genes between different cotton species is close, and the genetic structure in cotton is highly conservative. During the evolution of cotton, in addition to preserving the U-box domain, some other domains retain the basic functions of the family and enrich the diversity of the genes. The gene structure analysis showed that exon number of each *PUB* genes varied hugely from 1 to 25, which may be the result of directional evolution in function and structure of *PUB* gene during the long evolutionary process.

Many studies have shown that *PUB* genes play an important role in the process of stress resistance of plants, for example, the overexpression of *AtCHIP* gene in Arabidopsis results in its sensitivity to high temperature and low temperature [40], while *AtPUB18*, *AtPUB19*, *AtPUB22* and *AtPUB23* respond positively to drought [16, 38, 41]. In this study, two *PUB* genes *GhPUB85A* and *GhPUB45D* were cloned and identified. Significant expression difference revealed that the functions of homologous genes were similar, but their contributions were different. All results laid a foundation for the study of *PUB* genes of cotton in future.

Figures

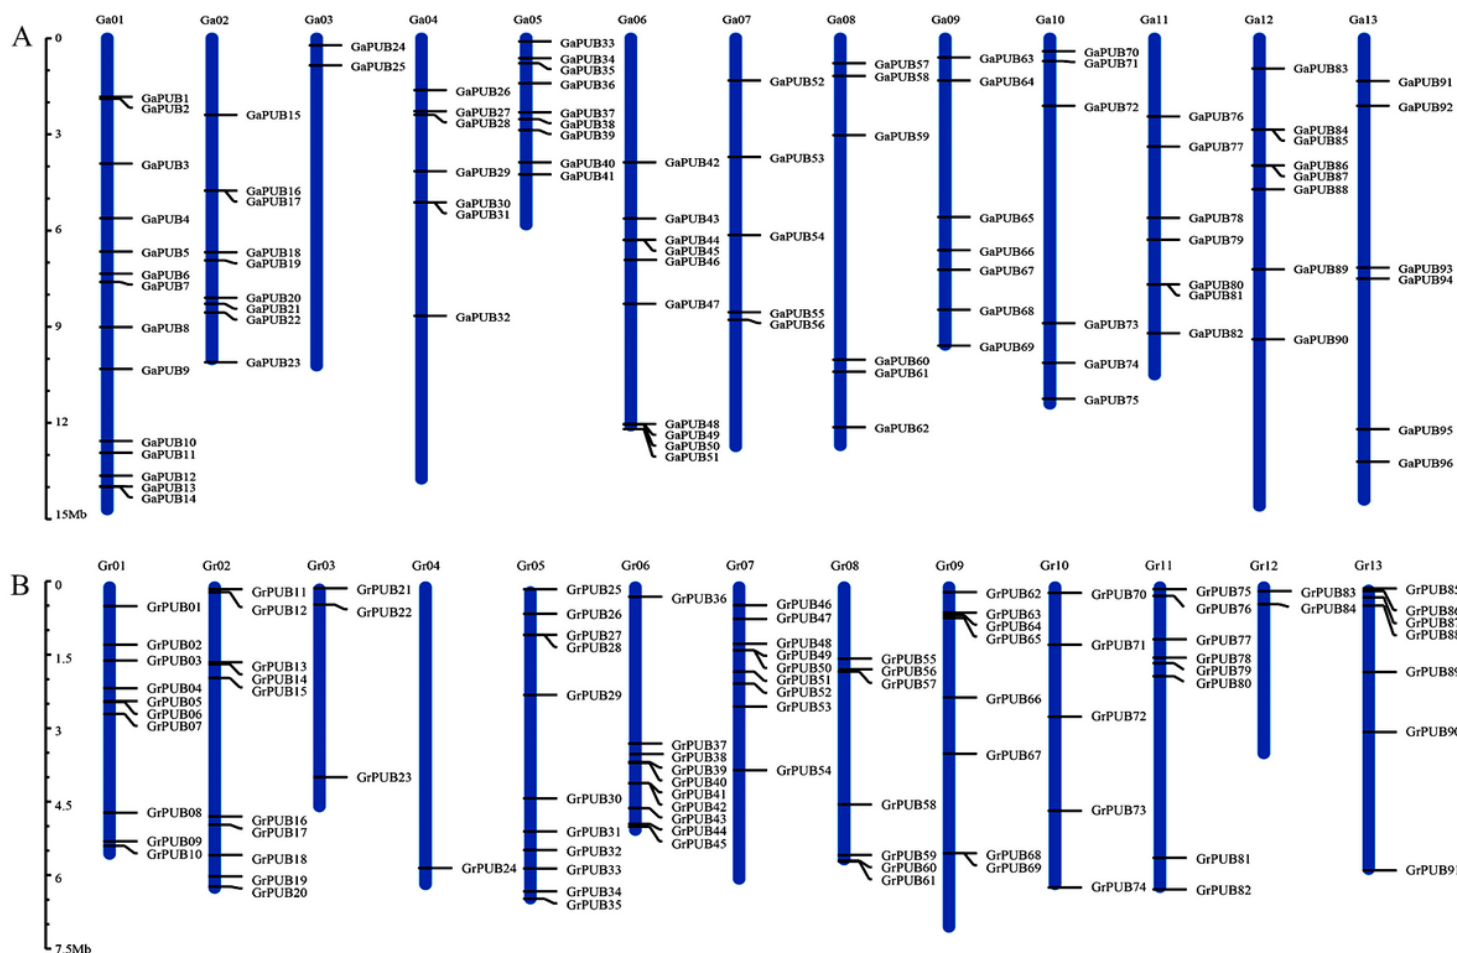

Figure 1

Locations of PUB genes on chromosomes in *G. raimondii* and *G. arboreum* Ga01-Ga13 and Gr01-Gr13 represent the chromosome 1 to chromosome 13 in *G. arboreum* and *G. raimondii*, respectively.

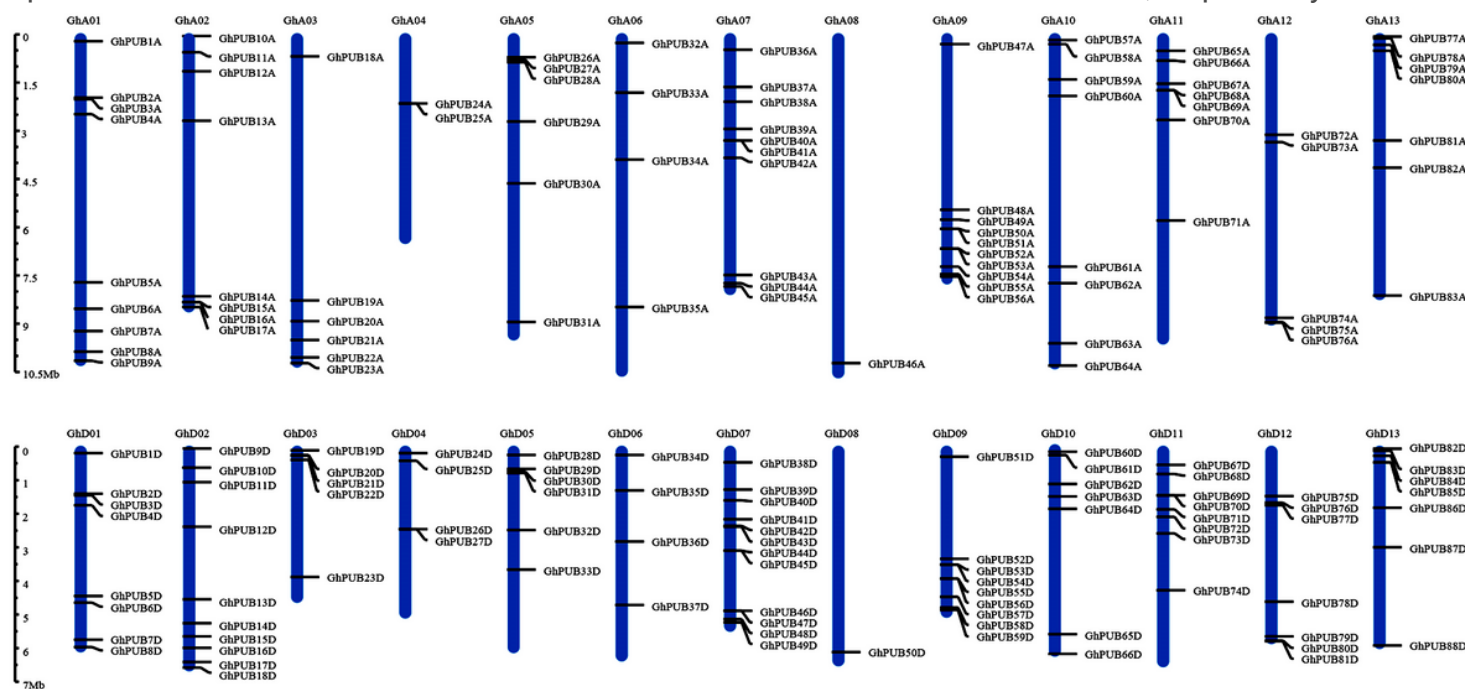

Figure 2

Locations of PUB genes on chromosomes in in *G. hirsutum* Replace the chromosome 1 to chromosome 13 of A subgenome of *G. hirsutum* with GhA01-GhA13, Replace the chromosome 1 to chromosome 13 of D subgenome of *G. hirsutum* with GhD01-GhD13.

Figure 3

Expression patterns of GhPUB68A, GhPUB85A, GhPUB45D and GhPUB69D during the drought, salt or low temperature stress a, b and c represent drought, salt and low-temperature treatment, respectively. Different letters from A to S indicate significance expression of different genes during different stresses ($p < 0.01$).

Figure 4

Subcellular localization of GhPUB85A and GhPUB45D

a

b

c

d

Figure 5

The phenotype of cotton leaves after virus infection and expression patterns of GhPUB45D and GhPUB69D under the drought, salt and low temperature stress. Different letters from A to K indicate significance expression of different genes during different stresses ($p < 0.01$).
