Abstract

Background: Duck hepatitis A virus type 1 (DHAV-1) causes a highly contagious disease in domestic ducklings, which is traditionally characterized by lesions in the liver and rarely in the pancreas. However, several outbreaks of DHAV-1, which were characterized by yellow coloration and hemorrhage in pancreatic tissues, have occurred in China. The causative agent was named as pancreatitis-type DHAV-1. Genomic sequencing indicated variation rates of 3.4-6.5% in the genome of the pancreatitis-type DHAV-1 compared with those of the classical type DHAV-1. The antigenic relationship between the pancreatitis-type DHAV-1 and classical type DHAV-1 indicated large variation. However, the mechanism involved in infection of the pancreatitis-type DHAV-1 is still unclear.

Results: In the present study, transcriptome analysis of duck pancreas infected with classical type DHAV-1 and pancreatitis-type DHAV-1 was carried out. Following deep sequencing with Illumina-Solexa, a total of 53.9 Gb clean data were obtained from the cDNA library of the pancreas and a total of 29,597 unigenes with an average length of 993.43 bp were generated following *de novo* sequence assembly. The expression levels of D-3-phosphoglycerate dehydrogenase, phosphoserine aminotransferase, phosphoserine phosphatase, which are involved in glycine, serine and threonine metabolism pathway, were significantly downregulated in the pancreatitis-type DHAV-1-infected group compared with those of the classical type DHAV-1-infected group.

Conclusion: These findings provide information regarding differential expression levels of metabolism-associated genes between pancreatitis-type DHAV-1 and classical type DHAV-1, indicating that intensive metabolism disorders may contribute to different subtypes of DHAV-1-infection.

Background

Duck viral hepatitis (DVH) is a highly fatal contagious disease of ducklings, characterized by clinical signs of opisthotonos and by liver hemorrhagic lesions [1]. This causes mortality rates of approximately 95% in ducklings within a week. The causative agents of DVH include duck hepatitis virus type 1 (DHV-1), DHV-2 and DHV-3. Recently, DHV-1 along with two other types was classified as the species *Avihepatovirus A* of the genus *Avihepatovirus* in the family *Picornaviridae* and was renamed as duck hepatitis A virus (DHAV) [2]. DHAV is divided into three genotypes as follows: DHAV-1, DHAV-2 and DHAV-3.

To the best of our knowledge, DHAV-1 is distributed worldwide and DHAV-2 has been isolated only in Taiwan to date [3, 4]. The presence of DHAV-3 was mainly reported in Korea and China [5-8]. Generally, the lesion in the liver is a typical lesion of DVH caused by DHAV-1. However, Guérin et al. reported that several DHV-infections of young Muscovy ducklings exhibited nervous symptoms and pancreatitis in 2005 [9]. Several outbreaks of DHAV-1, which were characterized by yellow coloration and hemorrhage in pancreatic tissues, have occurred in China in 2011 [10]. The causative agent was subsequently named as pancreatitis-type DHAV-1. Genomic sequencing indicated a variation rate of 3.4-6.5% in the genome of

pancreatitis-type DHAV-1 compared with that of classical type DHAV-1 [11]. The antigenic association between the pancreatitis-type DHAV-1 and the classical type DHAV-1 indicated large variation, and the pancreatitis-type DHAV-1 was subsequently noted as DHAV-1 subtype [12]. The comparative pathogenicity of DHAV-1 and DHAV-1s strains in the ducklings of different species has been well documented [13, 14]. The mechanism involved in infection of the pancreatitis-type DHAV-1 is still unclear. The host response to the pancreatitis-type DHAV-1 infection requires experimental validation.

The host-pathogen interaction is a complex and dynamic biological system with its outcome depending on the microbial pathogen properties to establish infection and the ability of the host to control infection [15]. However, several aspects of pancreatitis-type DHAV-1-host interactions remain to be clarified. Transcriptomics is the analysis of genome-wide RNA expression and is an available approach to characterize host and pathogen processes in infectious diseases. This method also provides a clear understanding of the host defense mechanisms during the viral infection. To date, the data on the transcriptome profile of the duck pancreatic tissue and its response to viral infection at the transcriptome level are lacking. Moreover, the differences of host responses to the classical type DHAV-1 and the pancreatitis-type DHAV-1 have not been reported to date.

In the present study, transcriptome sequencing was applied to determine the gene transcriptome pattern of duck pancreatic tissues infected with the classical type DHAV-1 and the pancreatitis-type DHAV-1. Dramatic differences were observed in the genes involved in the glycine, serine and threonine metabolism pathway, indicating that intensive metabolism disorders may contribute to the different subtypes of DHAV-1-infection.

Results

Gross lesions of the classical type DHAV-1 and the pancreatitis-type DHAV-1-infected ducklings

The infection experiments were conducted with the pancreatitis-type DHAV-1 GD1206 and the classical type DHAV-1 FZ86 strains at the dose of $10^{5.0}$ ELD₅₀ per ducks. The ducks infected with the classical type DHAV-1 FZ86 strain indicated clinical symptoms of depression, lethargy, and opisthotonos. The major lesions that were typically enlarged with petechial and ecchymotic hemorrhages in the liver and kidney were observed during necropsy. No visible lesions were noted in the pancreas. In contrast to these observations, the ducklings infected with the pancreatitis-type DHAV-1 GD1206 strain demonstrated no typical signs during the course of infection. The major affected organ in the pancreatitis-type DHAV-1 group was the pancreas, which exhibited lesions of yellowing or hemorrhage. No hemorrhagic change was noted in the liver of the pancreatitis-type DHAV-1-infected ducklings. No gross lesions were observed in the mock-infected control group. The pancreatic samples were the classical type DHAV-1- or the pancreatitis-type DHAV-1-positive in the classical type DHAV-1- or the pancreatitis-type DHAV-1-group as determined by reverse transcription polymerase chain reaction (RT-PCR) analysis.

RNA-seq and assembly of transcriptome data from the pancreas of the ducklings

Following Illumina-Solexa deep sequencing, a total of 183 M raw reads were obtained in the cDNA library derived from pancreatic tissues. The removal of low-quality reads (i.e., reads containing only adaptors and empty reads) resulted in the identification of clean reads with total residues of 53.9 Gb clean data. Following *de novo* sequence assembly, a total of 29,597 unigenes with an average length of 993.43 bp were generated. BLAST and ORF analyses indicated that only 9,387 targets matched the known genes among the total number of unigenes. The sequencing data from the GD1206- and FZ86-infected groups were submitted to the NCBI database (accession number: SRR7239978, SRR7239979, SRR7239984, SRR7239985, SRR7239988, and SRR7239989).

The heatmaps indicated the top differentially expressed genes (DEGs) and the classification of gene expression profiles in different subtype DHAV-1-infection (Figures 1). In order to obtain a global view of the change in duck gene expression among different experimental groups, three paired comparisons (classical type DHAV-1 vs. control, pancreatitis-type DHAV-1 vs. control, pancreatitis-type vs. classical type DHAV-1) were performed. RNA-seq analysis detected 3,340 and 5,919 genes, which were expressed at significantly different levels in classical type DHAV-1- and pancreatitis-type DHAV-1-infected animals, respectively compared with those noted in the control group ($P < 0.05$). Classical type DHAV-1 infection contributed to the differential expression of 2,031 genes that were upregulated and 1,309 genes that were downregulated in the pancreatic tissues of the infected animals compared with those noted in the control ducklings. Moreover, the expression levels of 3,308 genes were upregulated and those of 2,611 genes were downregulated in pancreatitis-type DHAV-1-infected animals. A total of 1,913 genes were differentially expressed in pancreatitis-type DHAV-1-infected animals compared with classical type DHAV-1-group. Specifically, the expression levels of 834 genes were downregulated and those of 1,079 genes were upregulated (Figure 2).

Functional analysis of the transcriptome data derived from the pancreatic tissues of different subtype DHAV-infected animals

We performed GO enrichment analysis by functional annotation clustering of DEGs and annotated DEGs into three groups, including biological processes (BP), cellular components (CC), and molecular function (MF).

The putative functions of the unigenes in the libraries derived from the classical type DHAV-infected ducklings were analyzed using GO. The analysis of the GO categories of the classical type DHAV-1-group indicated that the differentially expressed genes were mapped to 61 categories of BP, CC and MF (Figure 3A). The categories of BP included the genes mainly involved in the positive regulation of interleukin-12 production, myeloid leukocyte activation and T cell proliferation. The majority of the corresponding genes in the CC categories were involved in the external side of plasma membrane, the oligosaccharyltransferase complex and the integral component of the membrane. The majority of the corresponding genes in the MF categories were involved in the non-membrane spanning protein tyrosine kinase activity, antioxidant activity and calcium-dependent phospholipid binding.

The putative functions of the unigenes in the pancreatic libraries of the pancreatitis-type DHAV-1 infection were analyzed using GO. The analysis of the GO categories indicated that the differentially expressed genes were mapped to 61 categories including BP, CC and MF (Figure 3B). The majority of the corresponding genes in the BP categories were involved in cholesterol efflux, positive regulation of cell cycle and translation. The categories of the CC included genes that were mainly involved in the cytosolic large ribosomal subunit, extracellular space and ribosome. The majority of the genes of the MF categories included genes involved in the structural constituents of the ribosome, cytokine activity and NADH dehydrogenase (ubiquinone) activity.

The putative functions of the unigenes in the pancreatic libraries of the pancreatitis-type DHAV-1-infected ducklings were compared with those of the classical type DHAV-1-infected ducklings and were analyzed using GO. The analysis of the GO categories indicated mapping of differentially expressed genes to 61 categories of BP, CC and MF (Figure 3C). The BP category included mainly genes that were involved in the oxidation-reduction process, the negative regulation of apoptotic process and the myeloid leukocyte activation. The CC category included mainly genes that were involved in the extracellular space, protein-extracellular matrix and ribosome. The majority of the corresponding genes in the MF category were involved in the antioxidant activity, G-protein coupled peptide receptor activity and structural constituents of the ribosome.

Pathway analysis of DEGs based on KEGG following different DHAV-1-infection

The KEGG database was used to analyze specific pathways in order to further define DEG function in the duckling pancreatic tissue following different subtype DHAV-1-infections. The top 20 enrichment KEGG pathways were listed in Figure 4 according to their Q-value ($Q < 0.05$) (Table 1).

Table 1 Signal pathway enrichment evaluated by KEGG in the pancreas of the ducklings in classical type DHAV-1 vs. control, pancreatitis-type DHAV-1 vs. control, pancreatitis-type DHAV-1 vs. classical type DHAV-1

Group	Pathway	DEG in Pathway	All Gene in Pathway	P-value	Q-value
Classical type DHAV-1 vs. control	Influenza A	55	134	1.58E-10	3.48E-08
	Cytokine-cytokine receptor interaction	56	144	1.24E-09	2.73E-07
	Protein processing in endoplasmic reticulum	66	187	4.65E-09	1.02E-06
	Intestinal immune network for IgA production	20	31	1.03E-08	2.27E-06
	Phagosome	53	144	3.26E-08	7.18E-06
	Cell adhesion molecules (CAMs)	44	111	3.98E-08	8.76E-06
	JAK-STAT signaling pathway	44	120	5.58E-07	0.000123
	Toll-like receptor signaling pathway	29	83	0.000132203	0.029085
Pancreatitis-type DHAV-1 vs. control	Cytokine-cytokine receptor interaction	74	144	3.43E-08	8.44E-06
	Influenza A	67	134	5.84E-07	0.000144
	Toll-like receptor signaling pathway	42	83	5.28E-05	0.012986

	Focal adhesion	33	243	0.000311296	0.04327

A total of 6 functional categories were identified that played important roles in the classical type DHAV-1 FZ86- and the pancreatitis-type DHAV-1 GD1206-mediated infections. These categories were mainly classified into immune system categories, including the Toll-like receptor signaling pathway. However, significant KEGG enrichment in the pancreatitis-type DHAV-1 group was also involved in the metabolism function, including the glycine, serine and threonine metabolism pathway.

Verification of DEG identification by real-time RT-PCR

In order to verify the differential gene expression levels obtained from the transcriptome sequencing data, we analyzed the expression levels of 10 genes that were involved in immune and metabolism-associated functions. These genes were also involved in host immune defense responses and metabolic function noted in the two subtype DHAV-1 infection groups. The genes examined were as follows: GNMT-like, GCAT, CBS, PHGDH, SERCA, PLC γ , TLR2, TLR4, TLR7 and IFN α . They were differentially expressed

compared with the control ones ($P < 0.05$), indicating the reliability of the transcriptome sequencing data (Table 2).

Table 2 Verification of real-time RT-PCR for some differentially expressed genes

Gene	Abbreviation	Transcriptomics fold change (\log_2FC)		Real-time RT-PCR fold change ($2^{-\Delta\Delta CT}$)	
		DHV-1/control	DHV-1a/control	DHV-1/control	DHV-1a/control
Glycine N-methyltransferase-like	GNMT-like	-2.08	-5.72	0.210	0.01
Glycine C-acetyltransferase	GCAT	-2.11	-4.80	0.20	0.04

Toll-like receptor 7	TLR7	5.81	5.36	45.57	30.27
Interferon alpha	IFN α	2.23	2.62	3.89	8.06

Discussion

In the present study, the ducklings that were inoculated with the classical type DHAV-1 FZ86 indicated massive haemorrhages on the liver surface. The ducklings that were inoculated with the pancreatitis-type DHAV-1 GD1206 strain exhibited loss of appetite, lying prone, diarrhea and depression. The gross lesion of the yellowed or hemorrhagic pancreatitis was observed in the pancreatitis-type DHAV-1-infected ducklings. However, no consistent nervous disorders were observed in the present study, which was not in line with the observations performed by Guérinet al. [9]. Cha et al. described that a DHAV-3 strain induced only liver discoloration without hemorrhagic mottling, lymphocyte infiltration and bile duct hyperplasia as determined by histology of the lesions [16]. These studies revealed the diversity in the pathogenicity of DHAV.

Transcriptome analysis is a promising tool that can provide a comprehensive understanding of the molecular mechanisms involved in specific biological processes and diseases [17]. Previous studies have described the transcriptome profile of DHAV-, Reovirus- and DHBV-infection in ducks [18-21]. In the present study, transcriptome sequencing was employed to explore and compare the gene expression patterns of infection with different subtype DHAV-1 in duck pancreatic tissues, with the aim to compare different molecular events during the pancreatitis-type DHAV-1 infection.

Following analysis of the clean reads with BLAST and ORF, a total of 9,387 matched known genes were obtained. The DEGs were annotated and categorized by GO and KEGG signaling pathway analyses, which demonstrated that the majority of these genes in classical type DHAV-1- and pancreatitis-type DHAV-1-infection groups were classified into immune system and metabolism categories. The investigation of the transcriptome of classical type DHAV-1-infected and the control ducklings indicated that classical type DHAV-1 infection caused downregulation of the expression of genes associated with metabolic pathways and inhibition of the metabolism of the host cell. In addition, upregulation of the expression levels of the immune-associated genes was noted that resulted in inhibition of viral replication and progression of viral infection [22]. Similarly, in the present study, upregulation of the expression of immune genes and downregulation of certain metabolism-related genes were observed in the pancreatitis-type DHAV-1 infection group compared with the corresponding levels noted in the control group. However, significant KEGG enrichment was noted in the pancreatitis-type DHAV-1 infection group compared with classical type DHAV-1 infection group that was mainly involved the metabolism function, including the glycine, serine and threonine metabolism pathway. The results suggested that the differences in the metabolism function of the DHAV-infection group may contribute to the different subtypes of DHAV-1.

D-3-phosphoglycerate dehydrogenase (PHGDH), phosphoserine aminotransferase (PSAT) and phosphoserinephosphatase (PSP) are involved in the three-enzyme step-serine biosynthesis [23]. Initially, 3-phosphoglycerate is converted to 3-phosphohydroxypyruvate by the enzyme PGDH. Subsequently, PSAT converts 3-phosphohydroxypyruvate to 3-phosphoserine. Finally, 3-phosphoserine is converted to L-serine by PSP [24]. L-serine is an important precursor involved in various processes, such as synthesis of proteins and phospholipids as well as the synthesis of tetrahydrofolate metabolites and specific amino acids, namely glycine, cysteine and D-serine [27, 28]. Previous studies have shown that L-serine supplementation can attenuate alcoholic fatty liver formation in mice and rats [27]. In the present study, the expression levels of the PHGDH, PSAT and PSP genes were significantly downregulated in the pancreatitis-type DHAV-1-infected ducklings compared with those noted in the classical type DHAV-1 group, indicating that serine metabolism disorders were involved in the pancreatitis-type DHAV-1 infection.

L-serine dehydratase (SDH) catalyzes the deamination of L-serine to yield ammonia and pyruvate. This enzyme uses L-threonine as a substrate to yield 2-oxobutanoate, which is a part of the valine, leucine and isoleucine biosynthetic pathway. The downregulation of serine dehydratase levels suggested that the pathway of serine to pyruvate was impaired and that it further affected the valine, leucine and isoleucine biosynthetic pathway [28-30].

The innate immune system is essential for recognizing pathogen infections and for the establishment of effective host defense. During the process of innate immune response, highly conserved pathogen-associated molecular patterns (PAMP) are detected by pattern recognition receptors (PRR)[31]. Three classes of PRRs have been shown to be involved in the recognition of virus-specific components in innate immune cells, namely Toll-like receptors (TLRs), retinoic acid-inducible gene I (RIG-I)-like receptors (RLRs)

and nucleotide oligomerization domain (NOD)-like receptors (NLRs)[32]. In the present study, almost similar innate immune responses were observed in both subtypes from DHAV-1 infected animals.

TLRs play a critical role in innate immune responses. In recent years, the role of innate immunity and its interaction with adaptive immunity has been mainly explored. In the TLR pathway, TLR2 plays a critical role in the induction of innate and inflammatory responses [33, 34]. Although TLR2 recognizes various bacterial components, recent studies have indicated that TLR2 is triggered by the HCV protein core and NS3 leading to the activation of inflammatory cells [35, 36]. In the present study, the expression levels of the TLR2 gene were 10.63- or 7.62-fold higher than those of the control group ducklings in the pancreatitis-type DHAV-1/classical type DHAV-1 infection groups, respectively, indicating that TLR2 may be involved in the host response to DHAV infection. TLR4 and CD14 have recently been shown to be the major lipopolysaccharide (LPS) receptors. Mutations in mouse and human TLR4 were found to be associated with hyporesponsiveness to LPS and confer an increased risk of gram-negative infections [37-39]. In addition to the interaction with LPS, the TLR4/CD14 complex interacts with other viruses and proteins, such as the respiratory syncytial virus and fibrinogen [40-42]. In the present study, the TLR4/CD14 expression levels in the pancreatitis-type DHAV-1 and classical type DHAV-1 infection groups were highly upregulated compared with those of the non-infected ducklings, indicating that TLR4/CD14 may be involved in the host response to pancreatitis-type DHAV-1 and classical type DHAV-1 infection. Surprisingly, TLR4 expression was significantly higher in the pancreatitis-type DHAV-1 and classical type DHAV-1 groups compared with that in the mock group with an increase of 51.63- and 38.59-fold, respectively. TLR7 can detect single stranded RNA (ssRNA) molecules and induce pro-inflammatory factors, such as the type I interferon to stimulate the body's non-specific immune response. Activation of TLR7 initiates downstream signaling cascades via induction of transcription factors, such as IRF7. This induces the production of pro-inflammatory cytokines and chemokines that are involved in various viral infection outcomes, including spontaneous clearance and viral persistence [43]. The potential implication of TLR7 in the innate immune response against hepatitis C virus was postulated [44, 45]. Nazmi et al. suggested that the TLR7 response following Japanese encephalitis viral infection promoted type-1 interferon production and generation of an antiviral state, contributing to the protective effect of systemic infection [46]. In the present study, upregulation of the expression levels of TLR7, IRF7 and IFN- β was noted in the pancreatitis-type DHAV-1 and classical type DHAV-1 groups, which was consistent with the findings described in previous studies [46, 47].

Conclusions

In the present study, transcriptome analysis of pancreatic tissues derived from classical type DHAV-1 and/or the pancreatitis-type DHAV-1-infected ducks was reported. The infection of the pancreatitis-type DHAV-1 caused yellowing and hemorrhagic lesions in the pancreatic tissues of the ducklings and was associated with differences in the expression levels of D-3-phosphoglycerate dehydrogenase, phosphoserine aminotransferase and phosphoserine phosphatase, which are involved in the glycine, serine and threonine metabolism pathway. The expression levels of the aforementioned genes were significantly downregulated in the pancreatitis-type DHAV-1-infected group compared with those from the

classical type DHAV-1-infected group, indicating that intensive metabolism disorders may contribute to the different subtypes of DHAV-1 infection.

Methods

Animal Experiment

One-day-old male Muscovy ducklings (*Cairina moschata*) were purchased from a commercial hatchery farm. Each duckling had free access to food and water and shared the same environmental conditions at 35°C. The temperature was decreased by 1°C every day. The light was continuously available during the animal experiments. Serum samples and cloacal swabs were collected from the ducklings prior to viral challenge. The presence of antibody and antigen was determined using indirect enzyme linked immunosorbent assay (ELISA) and RT-PCR methods [10], respectively in order to confirm that the animals were classical type DHAV-1 and the pancreatitis-type DHAV-1 negative. Four days later, 60 5-day-old healthy Muscovy ducklings, which were negative for classical type DHAV-1 and pancreatitis-type DHAV-1 antigens and antibodies, were randomly divided into three groups ($n=20$ for each group). The ducklings in each group were challenged intramuscularly with $10^{5.0}$ ELD₅₀ (50% egg lethal dose) classical type DHAV-1 FZ86 strain and pancreatitis-type DHAV-1 GD1206 strain in 200 µl phosphate buffer saline (PBS) or mock-infected with PBS. Each group of ducklings was housed in separate isolators (Suzhou Fung's laboratory Animal Equipment Co., Ltd.) with free access to food and water throughout the experimental period. Each group of ducklings shared the same environmental conditions at an experimental temperature of 31°C. The temperature was reduced by 1°C every day until 25°C. The light was continuously available during the animal experiments. The daily clinical symptoms were monitored.

At 24 h post-inoculation, six ducklings in each group were randomly selected. The ducklings were administered sodium pentobarbital (40 mg/kg bodyweight; Sigma-Aldrich, USA) intravenously and subsequently the animals were humanly sacrificed under narcosis [47]. The pancreatic samples were harvested and pooled into two tubes (3 samples/tube, 0.5 g each sample) for transcriptional analysis. Concomitantly, the pancreatic samples were also detected by RT-PCR in order to confirm classical type DHAV-1- or pancreatitis-type DHAV-1 infection. The remaining 14 ducklings of each group were observed for three days. At the end of the observation period, the ducklings were administered intravenously sodium pentobarbital (40 mg/kg bodyweight; Sigma-Aldrich, USA) and subsequently humanly sacrificed under narcosis [47]. The gross lesions were observed.

Host gene expression associated with pancreatitis-type DHAV-1 infection

RNA extraction, library construction, and sequencing

Total RNA was extracted using RNAiso Plus Total RNA extraction reagent (TaKaRa, Shiga, Japan) according to the manufacturer's instructions. RNA degradation and contamination was monitored on 1.0% agarose gels. RNA purity was confirmed using the NanoPhotometer® spectrophotometer (IMPLEN, CA, USA). RNA concentration was measured using the Qubit® RNA Assay Kit in a Qubit®2.0 Fluorometer

(Life Technologies, CA, USA). RNA integrity was assessed using the RNA Nano 6000 Assay Kit of the Agilent Bioanalyzer 2100 system (Agilent Technologies, CA, USA) and subsequently employed as a template for the synthesis of double-stranded cDNAs. Sequencing libraries were generated using NEBNext®Ultra™ RNA Library Prep Kit for Illumina® (NEB, CA, USA) following the manufacturer's recommendations. Finally, index codes were added to the attribute sequences of each sample. The clustering of the index-coded samples was performed on a cBot Cluster Generation System using TruSeq PE Cluster Kit v3-cBot-HS (Illumina) according to the manufacturer's instructions. Following cluster generation, the library preparations were sequenced on an Illumina HiSeq 4000 platform and paired-end reads were generated. Raw reads were filtered and assembled using Trinity software, and then the transcript library was obtained. The quantitative relationship between the transcript and the genes was analyzed. With the bowtie and RSEM software, we calculated expression value using pairing the reads in the transcript library and obtained the count value. According to the length of the transcript, the count of expression was normalized. The RNA-seq data from this study were submitted to the NCBI Sequence Read Archive (SRA) (<http://www.ncbi.nlm.nih.gov/sra/>).

Transcriptome data analysis

Differential expression analysis of the three groups was performed using the DESeq R package (1.10.1). DESeq provided statistical routine methods for determining differential expression in digital gene expression data using a model, which was based on the negative binomial distribution. The resulting P-values were adjusted using the Benjamini and Hochberg's approach for controlling the false discovery rate. The genes with an adjusted P-value of <0.05, identified using DESeq, were assigned as differentially expressed genes.

GO enrichment analysis and KEGG pathway enrichment analysis

Gene Ontology (GO) enrichment analysis of the differentially expressed genes (DEGs) was implemented by the topGO R packages-based Kolmogorov–Smirnov test. The GO terms with the corrected *P* value less than 0.05 were considered significantly enriched in the differential expressed genes.

The Kyoto Encyclopedia of Genes and Genomes (KEGG) is a database resource for understanding high-level functions and utilities of the biological systems, such as the cell, organism and the ecosystem. Specific molecular-level information is collected notably from large-scale molecular datasets generated by genome sequencing and other high-throughput experimental technologies (<http://www.genome.jp/kegg/>) [48]. The KOBAS software was used to assess the statistical enrichment of differentially expressed genes in the KEGG pathways [49]. The KEGG terms with a corrected P-value (*Q*-value) less than 0.05 were considered significantly enriched in the differential expressed genes.

Verification by real-time RT-PCR

The expression levels of the differentially expressed genes were also assessed by real-time RT-PCR in order to confirm the sequencing data. The individual primer sequences of the 10 target genes and of the

internal reference gene (GAPDH) [50] were listed in Table 3. Following reverse transcription, a [SYBR®Fast qPCR Mix](#) (Takara, Beijing) and a Mastercycler ep realplex (eppendorf) were used according to the manufacturers' instructions. The reaction conditions were as follows: 95°C for 1 min, followed by 40 cycles of 95°C for 10 sec and 60°C for 40 sec. A final melt curve analysis was completed. The relative mRNA levels were compared to those of the mock-infected ducks and the mean values were calculated using the threshold cycle $2^{-\Delta\Delta CT}$ method [50]. The comparisons of the experimental groups were estimated by the Student's *t*-test with a two-tailed analysis in order to determine significant differences. *P*-values less than 0.05 were considered significant.

Figures

Figure 1

Heat map analysis used to classify gene expression patterns in classical type DHAV-1 FZ86 infection (A) and pancreatitis-type DHAV-1 GD1206 infection (B). Genes with similar expression patterns were clustered, as shown in the heat maps. Intensity of color indicated gene expression levels that were normalized according to Log2 FPKM value

Figure 2

Volcano plots of differentially expressed genes in the pancreas of the ducklings in classical type DHAV-1 vs. control (A), pancreatitis-type DHAV-1 vs. control (B), pancreatitis-type DHAV-1 vs. classical type DHAV-1 (C). Red points represented up-regulated genes, green points represented down-regulated genes, and blue points represented genes with no significant difference

Figure 3

GO classification of differentially expressed genes in the pancreas of the ducklings in classical type DHAV-1 vs. control (A), pancreatitis-type DHAV-1 vs. control (B), pancreatitis-type DHAV-1 vs. classical type DHAV-1 (C). Annotation statistics of differentially expressed genes in the secondary node of GO. The horizontal axis showed secondary nodes of three categories in GO. The left side of vertical axis displayed the percentage of annotated genes versus the total gene number and the right side showed the number of genes

Figure 4

Top 20 KEGG pathways enriched in the pancreas of the ducklings in classical type DHAV-1 vs. control (A), pancreatitis-type DHAV-1 vs. control (B), pancreatitis-type DHAV-1 vs. classical type DHAV-1 (C)
