Abstract

Background and aims.

Undergraduate involvement in research necessitates a better understanding of their potential as well as the anticipated barriers they will face. The objective of this study was to assess medical undergraduates' knowledge, attitudes, and research barriers.

Methods. A cross sectional study included medical students from the University of Tripoli, Libya, where a self-administered questionnaire was used to evaluate the students' knowledge, attitudes and perceived barriers. Filled questionnaires were received from the medical undergraduates of different faculties of medical specialties. Data were analyzed using descriptive statistics.

Results. A total of completed questionnaires were received from 120 undergraduate medical students. The overall result of knowledge among them was encouragingly good (51%). Majority of students taught that the main barriers in conducting research were lack of awareness (71.7%), lack of self-interest (56.7%), lack of faculty encouragement for research (84.2%), insufficient time (59.2%), and the difficulty in obtaining resources and data for research (68.3%).

Conclusion. Participants in the current study showed a moderate knowledge level with associated positive attitudes towards research. This attitude needs to be transformed into better knowledge and appropriate practice.

Introduction

In today's world, where medical progress is occurring at an unprecedented rate, staying up to date on advanced medical technologies has become critical. Therefore, health research has become an important component of medical education. Research also yields new findings with the potential to influence health care. Thus, encouraging medical students to conduct research as part of their medical careers can help them achieve self-sufficiency in healthcare and aid in the development process [1].

The updated knowledge of scientific principles and methods is essential for the conduct of research. Medical students should be aware of the methods in carrying out research as they will be future doctors who will have to practice evidence-based medicine in patient care. Scientific research is the systematic approach by which theories and hypotheses can be proved or disapproved [2]. Research in medicine has an impact on prevention, diagnosis, and newer treatment for the medical ailments. It has brought reforms in policies for health-care programs [3].

Medical research can be basic, applied, or translational research conducted to aid and support the development of knowledge in the field of medicine [4]. Medical knowledge and training should be up-to-date as they are important for doctors in their duty of care for patients and provide the best available effective treatment based on the 'best available evidence'. Also, every doctor should contribute in the
generation of evidence by conducting research [5]. Barriers to research among medical students were found to include: inadequate knowledge of study design, time limitations, restricted funding support, lack of research training, lack of mentors, lack of research self-efficacy, lack of interest, and limited access to data sources [6].

Unfortunately, the insufficient attention to research by a government and the educated members of a community may contribute to scientific and knowledge lags. The shortfall in basic and valuable research may reflect factors as attitude to, knowledge of and barriers toward research [7].

One of the most important factors for conducting research is the researchers’ beliefs, where attitude to health research come from the researchers’ curiosity and interest in a particular subject or their wish to solve a problem within a community, then the adequate knowledge about research principles. The final factor affecting the performance of research lies in the barriers against researchers. Previous studies of medical students showed that they had inadequate knowledge of the scientific inquiry process [7].

Given the emerging role of research in health care, it is imperative to conduct studies that signify the current status toward conducting research. Therefore, the present study was meant to assess the knowledge, attitude, and barrier towards research in medical students of Libya. By assessing these factors, we can help make research more appealing to medical students to increase the number of skilled researchers in the future

**Methods**

**Study design and setting**

This was a prospective questionnaire-based study conducted to assess the knowledge and attitude of medical students at the University of Tripoli, Libya toward research. Eligible criteria were students attended medical classes (Medicine, pharmacy, and health) at the University of Tripoli. Students from other non-medical or visitors were excluded. This study was approved by the research committee of the faculty of medical technology, University of Tripoli. Verbal consent form was to participated in this study were obtained from all participants.

**Questionnaire development and content**

About 120 questionnaires were distributed to medical students, aiming at their knowledge, attitude, and barrier towards research. The questionnaire was based on the previous study into three sections. The first section was related to the knowledge on research. The values of this section are knowledge of research through 10 questions ranging from basic knowledge of research types, knowledge of research writing methods, references, research problem, research objectives, and requirements for the ethics of scientific research.

The second section was about attitude, and was included questions to assess the situation and the questions were based on the perceived importance of the scientific right in the minds of students in
aspects of their education, life, and medical profession and the type of research they preferred.

Furthermore, the third section focused on barriers to research assessed through 5 questions. Questions focused on the factors that limit the student’s role in research, whether it is a lack of research ideas, problems in conducting research (ie lack of access to research equipment and materials), time constraints, etc.

**Statistical analysis**

Data were descriptively analyzed using SPSS (statistical package for social science). Data was presented as percentage and count.

**Results**

**Patient demographics**

A total of completed questionnaires were received from 120 undergraduate medical students. Among the study population, 52 (43.3%) respondents were males and 68 (56.7%) were females. Distribution of students depending on the study mode, were Medical 55 (45.8%), Pharm 22 (18.3%) and Health sciences 43 (35.8%) (Table 1).

**Medical students’ response towards knowledge**

The knowledge of research was investigated through 10 questions related to types of research, research hypotheses and problems, research references, and ethics of scientific research (Table 2). Majority of
student (60%) they know about the type of research. They also know (32.5%) the meaning of study hypothesis. Most of the students had insufficient knowledge of the research problem about (40.8%). Majority of student (80%) they know about the study of objectives.

With regard of the knowledge about statistical package social science we found that the majority of them around (57.5%) didn’t know what’s the meaning of SPSS. Similarly, most of them didn’t know what’s the meaning of PubMed (70.8%), PubMed is the major database for social academic students. Regarding the question about participate of research proposal most of participant students they know what is the meaning of research proposal (73.3%). Similarly, they also know the part of scientific paper around (51.7%).

Regarding the statement of citation type we found that the most of participate know about the citation types (55.8%). Likewise, the majority of them didn’t know the meaning of ethics of research (55.8%).

In table 3, attitudes towards the research were evaluated through 4 questions according to the student’s attitude regarding degree of the attitude. The results found that the majority of students (57.4%) they advise to have research as a part of MBBS curriculum. Also, most of them (88.2%) consent that the research will help in better understanding our subject. Similarly, the majority of them said that the research will help one’s clinical practice later (81.7%), minority of them consent that the research is not waste of time and dose not disturb studies (44.2%).

Table (3): Medical students’ response towards attitude domains
As shown in table 4, the barriers between the student and the research were evaluated through 5 questions. The question was summarized and then converted into a percentage to represent the barriers. The result was reported that the majority of them they have a lack of awareness (71.7%). Correspondingly, most of them lack of self-interest (56.7%). However, we found the majority of them said that there is a lack of faculty encouragement for research (84.2%). Majority of them said that there is a lack of time (59.2%). Also, we found the most of them said that there is a difficult to find resources and data for research (68.3%). investigated the barriers of students about medical research,

Discussion

Research is an extremely important element in the advancement of better health care services provided to the public. An adequate level of knowledge, positive attitude, and reasoning skills play an important role in carrying out research [8]. In this study, we aimed to assess the knowledge, attitude and barriers of medical students toward medical research throughout 120 medical students.
The overall result of knowledge among them was encouragingly good (51%), where about 60% of the students knew the types of research. This result was similar to another study conducted on undergraduate students in Egypt who have demonstrated moderate level of knowledge in terms of research [mean score 43.4%] [9].

In the current study, only 32.5% and 40.8% students knew the definition of research hypothesis and problem statement respectively, whereas 29.2% students knew the PubMed and 42.5% knew the statistical analysis tool SPSS. Nearly half of (51.7%) students knew what is parts of scientific paper, 55.8% of them knew the rule of citation types and 44.2% of them know the ethics meaning in the research. These findings were in agreement with the results of Wahdan et al., on students of Ain Shams University, Egypt, who reported moderate level of knowledge and attitude (mean score 43.4 + 22.5 and 45.8 + 18.6, respectively) [9]. Similarly, a study conducted by Vodopivec revealed that there is lack of knowledge on the scientific method and communication in medicine [10].

The attitude of participant towards medical research was investigated in the current study, and the findings exhibited that the majority of students (57.4%) they advise to have research as a part of MBBS curriculum. Also, most of them (88.2%) consent that the research will help in better understanding our subject. Similarly, the majority of them said that the research will help one's clinical practice later (81.7%), most of the students felt the importance of research in clinical practice and agreed to spend time for research. This finding was similar to the study done in south Africa that reported the importance of research interest by most of the participants [11]. Minority of them consent that the research is not waste of time and dose not disturb studies (44.2%).

The current study also investigated the barriers of students towards medical research, and reveled that the majority of them taught that the main barriers in conducting research were lack of awareness (71.7%), lack of self-interest (56.7%), lack of faculty encouragement for research (84.2%), insufficient time (59.2%), and the difficulty in obtaining resources and data for research (68.3%). In agreement to our study, Soe et al., showed that the majority of students cited barriers were the lack of time (79.9%), lack of knowledge and skills (72.1%), lack of funding (72.0%) and facilities (63.6%), and lack of rewards (55.8%) [12]. Evidence also showed that existence of barriers brings the gap between theory of scientific research and practice of conducting it [13]. The barriers to participate in scientific research can be classified as extrinsic [14] such as lack of training in research methodology, lack of time due to overburdened with educational activities, lack of rewards and incentives, lack of infrastructure and facilities, inadequate support by organization/institute, access to library and publications, and inadequate supervision and mentorship [15].

There were some limitations in this study, the study was conducted in one medical institution; therefore, the findings cannot be applicable to other institutions with the different environment. This was a cross-sectional study; therefore, we could neither observe the changes over time nor inference of causality.

Conclusion
The undergraduate medical students had moderate level of knowledge and positive attitudes toward medical research. Lack of awareness, lack of faculty encouragement for research, and the difficulty in obtaining resources and data for research were the major barriers. These barriers need to be addressed by providing proper supervision, research funding and awards, and providing access to electronic databases to encourage the undergraduate students participating in research activities. It is recommended to organize research workshops, frequent research presentations, and journal clubs to provide knowledge and skills needed for the medical students to implement the scientific research in the future.
