Abstract

Background: Type II diabetes is a major health problem worldwide, and is increasing in an alarming rate globally and in Ethiopia due to change in dietary habits and sedentary life style. Even though there is no effective cure for diabetes, early control of blood glucose significantly reduces the risk of diabetic complications. Different types of ingredients present in medicinal plants that act on a variety of targets by various modes and mechanisms are used to treat diabetes with minimum cost and side effect. Therefore, the objective of the present study was to investigate the antidiabetic effect of *Persea americana* mill fruit juice in high fat diet (HFD) and low dose Streptozotocin (STZ) induced type 2 diabetic (T2DM) male albino Wistar rats.

Methods: Thirty six male albino Wistar rats weighing form 150-200g were divided in into six different groups: group I (normal control); Group II (diabetic control); Group III (metformin control) and Group IV – Group VI (treatment groups). Group I was fed on standard pellet and group II – group VI were fed on HFD for 4 weeks to induce pre-diabetes and insulin resistance followed by low dose STZ injection to induce T2DM. The treatment groups (group IV, V and VI) were given 632 mg/Kg, 1264 mg/Kg and 1896 mg/Kg/day of *Persea americana* fruit juice for six weeks, respectively to compare with normal, diabetic and 7mg/Kg metformin treated groups. After forty-five days of treatment, the rats were fasted overnight (12 to 14 hours), anaesthetized and blood sample was collected by cardiac puncture for biochemical tests (fasting blood glucose (FBG), lipid profile, total protein and creatinine). The results were analyzed using SPSS version 22.0. One way ANOVA followed by Post hoc Tukey’s multiple comparisons were done to compare the mean differences among the experimental groups, and p-values < 0.05 were considered statistically significant.

Results: In high dose (1896 mg/Kg/day) *Persea americana mill* fruit juice treated group, food consumption, body weight, FBG, and LDL-C were significantly reduced and HDL-C was significantly increased (p < 0.005) compared with diabetic control group. Moderate dose (1264mg/Kg/day) treated group showed a decrease in FBG on 6th week and improve HDL-C levels. Treating the rats with *Persea americana* fruit juice changed TG, total protein and creatinine levels although not significant. Oral antidiabetes drug (metformin) significantly reduced pellet consumption, body weight, FBG and lipid profile.

Conclusion: Overall, *Persea americana mill* fruit juice showed antihyperglycemic and antihyperlipidemic effect particularly through reduction of fasting blood glucose, LDL-C and increasing HDL-C in T2DM induced rats, thus it can be helpful in reducing the risk of diabetic complications.

Background

Diabetes mellitus (DM) is a metabolic disorder, which either results from deficiency in insulin production by the pancreas or inability of the insulin produced to bind effectively to its receptor on the cell surface. Either of these conditions leads to accumulation of glucose in the blood and results in chronic hyperglycaemia (1, 2). Untreated chronic hyperglycaemia can in turn lead to long-term complications, including micro-vascular and macro-vascular problems that cause disturbances of carbohydrate, fat and protein metabolism, and it covers a wide range of heterogeneous diseases (3). World health organization (WHO) estimated that globally, 425 million adults aged over 18 years were living with diabetes in 2017 and this will increase to 629 million by 2045 (4). The diabetes prevalence in sub-Saharan Africa, which was 12.1 million in 2016 is expected to rise to 23.9 million by 2030 (5).
Diabetes mellitus could be categorized into several groups: type 1 diabetes mellitus (T1DM), type 2 diabetes mellitus (T2DM), gestational diabetes, and other specific types, but the vast majority cases of diabetes fall into T1DM and T2DM broad categories (6). Type 1 diabetes is arisen from absolute deficiency of insulin secretion while the more prevalent category, T2DM, is due to combination of resistance to insulin action and an inadequate compensatory insulin secretory response (7). Both T1DM and T2DM are characterized by hyperglycaemia, excessive urine production, compensatory thirst, increased fluid intake, blurred vision, unexplained weight loss, lethargy, and changes in energy metabolism (8).

Type 2 DM is the most common type of diabetes and accounts for 90-95% of all diabetic cases, and mostly prevalent in people older than 45 years who are overweight (9). It is characterized by a significant insulin production ranging from less than normal to above normal, but the body is unable to utilize it efficiently (9, 10). The change in dietary habits and a sedentary lifestyle are the two main causes responsible for the development of T2DM when insulin resistance is established as a precondition (1, 12).

Yet, there is no effective cure for diabetes, and the oral antihyperglycemic drugs and insulin currently used in managing the disease are associated with several undesirable side effects. The use of oral antidiabetic drugs is limited due to their adverse side effects such as the haematological, cutaneous and gastrointestinal reactions, hypoglycaemic coma and impairment of liver and kidney functions. In addition, they are not suitable to use during pregnancy (2, 8). Moreover, providing a modern medical healthcare across the world is still a far-off goal due to economic constraints (13).

Apart from the currently available therapeutic options, many herbal medicines have been recommended for the treatment of diabetes. A variety of ingredients present in medicinal plants are thought to act on a variety of diabetic targets by various modes and mechanisms (14). Many important drugs used in medicine today are directly or indirectly derived from plants due to its bioactive constituents such as; alkaloids, steroids, tannins and some plant phytochemicals, including cafestol, flavonoids and carotenoids (15).

*Persea americana* is the tree originated from Mexico and nowadays cultivated in different parts of the world, including Ethiopia (8, 13). The phytochemical constituents of *Persea americana* have been studied and analysis had shown the presence of polyphenols that has one to two times more protein than any other fruit, contains low amount of simple sugar and appreciable amount of dietary fiber, high in manganese, phosphorous, iron and potassium, but low in sodium, vitamin E, vitamin C, carotene, thiamin, riboflavin, nicotinic acid and folate (16). *Persia ameriana* fruit pulp has a various beneficial health effects such as anti-obesity, hepatoprotective, antiosteoarthritis, anti-carcinogenic effects, suppressing liver injury, wound healing activity and chemo-protective activities (17-21). It has also been reported to exhibit several pharmacological effects in ethnomedicine, including treatment for diarrhoea, intestinal parasites, skin and seed oil for weight loss (22, 23). Thus, the present study was aimed to investigate the antidiabetic effects of *Persia ameriana* fruit pulp juice in high fat diet and low dose SZT induced diabetic male albino Wistar rats.

**Methods And Materials**

**Study Design and Period**

An experimental study was conducted at animal laboratory of Biochemistry Department, College of Health Sciences, Addis Ababa University, Ethiopia from December 2018 to May 2019 to investigate the antidiabetic effect
of *Persea americana* fruit pulp juice in male albino Wistar rats.

**Ethical Consideration**

The study was conducted after the proposal was evaluated and approved by Department of Biochemistry Research and Ethical Review Committee (DRERC) by protocol no. M.Sc.13/17. All experimental activities conducted in the laboratory was in accordance to ethical declaration of national and international standards for experimental animals, which protect the right of experimental animal and minimize suffer, hunger, pain, thirst, injury, discomfort and fear to the best minimal level.

**Sample Size Determination**

An appropriate sample size determination is important since too small size misses the real effect in an experiment while a sample size larger than necessary will lead to wasting resources and ethical issues on sacrificed animals (24). Number of animals was calculated according to Federer rule :\((k-1) (n-1) \geq 15\) where \(k\), is the number of groups and \(n\), number of subjects per group; and drop-out size (do) was estimated 10%, the minimal size of sample was determined as: \(n_{do}= \frac{5}{(1-do)^2} = \frac{5}{(1-0.1)^2} = \frac{5}{0.81} = 6.2 \approx 6\) where \(n_{do}\) is minimal sample size (25). The size of sample in each group was at 6 rats. The study was conducted on six groups, so the total sample size was 6 groups \(\times\) 6 rats = 36 rats.

**Experimental Animals and Study Protocol**

Male albino Wistar rats (4-5 weeks) weighing 150-200 g were obtained from Department of Pharmacology, College of Health Sciences, Addis Ababa University. The animals were housed in polypropylene plastic cages and maintained under standard laboratory conditions of room/optimum temperature and 12 hour light/dark cycle at Biochemistry animal laboratory and fed on a standard commercial rat pellet and water *ad libitum*. At 9 - 10 weeks of age, the rats were randomly assigned into six groups. Throughout the experiment, each rat in the assigned group was identified by giving a specific number on its tail by permanent marker. The allocation and treatment of the rats were as follows:

**Group I**: Normal control rats injected citrate buffer and administered 3.5 ml/Kg of distilled water orally

**Group II**: HFD and STZ induced diabetic rats that served as diabetic control and were given distilled water daily.

**Group III**: HFD and STZ induced diabetic rats treated with 7 mg/Kg of metformin orally

**Group IV**: HFD and STZ induced diabetic rats treated with 632 mg/Kg of *Persea americana* fruit juice.

**Group V**: HFD and STZ induced diabetic rats treated with 1264 mg/Kg of *Persea Americana* fruit juice.

**Group VI**: HFD and STZ induced diabetic rats treated with 1896 mg/Kg-BW/day of *Persea Americana* fruit juice.

**High Fat Diet (HFD) Preparation**

Many experiments have used rats fed with commercial lard (animal fat) as an obesity model (26). However, since commercial lard is not available in Ethiopia, the HFD used in this experiment was prepared from locally available
bovine fat. To prepare the HFD, 40% purified fat was mixed with 60% of pellet (40%/60% w/w). Since the standard pellet powder consists of 20% fat, 60% carbohydrate and 20% protein (27), the final percentage of fat is 52% (i.e., 52%/100% W/W). Hence, the term, 'high fat diet' used in this study refers to a diet containing 52% fat, 36% carbohydrate and 12% of protein.

**Induction of Type 2 Diabetes Mellitus**

There are different methods to induce diabetes mellitus in animal model (28). In our study, high fat diet (HFD) and low dose streptozotocin (STZ) induced diabetic rat model was used. This model involves a combination of a high fat diet to bring about hyperinsulinemia, insulin resistance and glucose intolerance followed by treatment with the β cell toxin STZ, which results in a severe reduction in functional β cell mass. These two stressors were designed to induce the features of human T2DM pathology to the rats within a shorter period of time scale.

**Streptozotocin Injection**

After 4 weeks of dietary manipulation, the rats were fasted overnight and injected intraperitoneally with freshly prepared STZ at a concentration of 35 mg/Kg body weight in 0.1M citrate buffer (pH = 4.5). The rats were given 5% glucose solution from 4 to 8 hours to reduce STZ induced hypoglycemia (29), and fasting blood glucose was determined after 72hrs by glucometer. The rats with blood glucose level above 200 mg/dL were considered as diabetic and those with normal blood glucose level were re-injected STZ to induce T2DM.

**Preparation of *Persea americana* Fruit Juice and Dosage Calculation**

*Persea americana mill* fruit was purchased from Jimma town, 350 Km South West of Addis Ababa, Ethiopia and identified by taxonomists in national herbarium, Addis Ababa University. The ripen fruit was washed carefully with distilled water and cut off by spoon, peeled off and the seed removed. Then the edible part of fruit was mixed by blender to prepare a juice as consumed by humans. In our study, *Persea americana* juice was used to treat diabetic induced male albino Wistar rats. The juice was prepared by adding water to 80gm of wet fruit pulp up to 200ml mark. Then the juice was dried to know the weight of the fruit powder that is found in juice. The dry mass of the fruit in 200ml juice was found to be 44.5gm. The volume of juice given to rats was also extrapolated from volume of human daily consumption, which is (200ml of juice /day in 70Kg). In this study the average body weight (BW) of rats were 250gm. Therefore, the volume of juice given to rats was 0.71ml. The approximate amount of *Persea americana* fruit pulp powder in 0.71ml of juice is approximately158mg. Accordingly, 158mg, 316mg and 474mg /250gm BW/day was considered as a low, moderate and high dose of *Persea americana* fruit pulp juice, respectively. Similarly, 0.7, 1.4 and 2.1ml/250gm BW/day were considered as low, moderate and higher volume that is given to rats daily. The doses (158mg, 316mg and 474mg /250gm BW/day) were converted to standard unit (mg/Kg) as 632, 1264, and 1896mg/Kg/day, respectively and used in this thesis document. The *Persea Americana* fruit juice was administered for six weeks orally from 9:30-10:30 AM.

**Extrapolation of Metformin Dose**

Safe and effective drug dosing is necessary regardless of its purpose of administration. There are several instances where in the initial dose of a particular drug is unavailable in a specific species. Therefore, choosing starting dose of such drugs for research, experiments, or clinical trials in animals and humans is a concern. The human dose of metformin drug was extrapolated to animal dose as follows (30).
Blood Sample Collection, Serum Preparation and Storage

At the end of the experiment, the rats were fasted overnight and euthanized by anesthetizing with diethyl ether and then blood was collected by direct cardiac puncture to serum separator tube. Then, the blood was left at room temperature for 30 minutes to coagulate and centrifuged at 3000 rpm for 10 minutes. The serum sample was transferred to necked tube and stored in deep freezer at -80 °C until the biochemical analyses were done.

Biochemical Tests

Total cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-C), total protein (TP) and creatinine were determined with chemistry analyzer. Low density lipoprotein cholesterol (LDL-C) level was calculated using Frieldwald's formula (31). Overnight fasting blood glucose was collected from the tail of the rats, and measured with One Touch GlucoSure on 0, 14th, 28th and 42th days of the experiment.

Statistical Data Analysis

The statistical data were analyzed using SPSS version 22.00. The results of food consumption, body weight and biochemical parameters were expressed as mean ± SEM. The statistical differences between the means were examined using analysis of variance (ANOVA) followed by Post Hoc Tukey's multiple comparisons. The p-values < 0.05 were declared as statistically significant.

Results

Effect of *Persea americana* on Food Intake

The food intake of diabetic control group rats was significantly increased \( (p = 0.001) \) when compared with normal control group. In high dose treated group, the mean pellet consumption was significantly reduced when compared with diabetic control group \( (p = 0.004) \). However, no significant difference was observed in moderate and high dose treated group compared to the normal control group (Table 1).

group; * - significant difference between all groups as tested by one way ANOVA. The superscript letters “a” and “b” indicate the significant differences compared to normal control and diabetic control groups, respectively.

**Effect of *Persea americana* on Body Weight**

Before the induction of T2DM, there was no significant difference in the mean values of body weight among all groups of the rats. However, at the end of experiment, the mean body weight of diabetic control, low dose *Persea americana* and metformin treated groups significantly decreased compared to body weight of normal control group ($p = 0.001; 0.007$ and $0.044$), respectively. Interestingly, the mean body weight of high dose treated group significantly increased compared with that of diabetic control group ($p = 0.002$). There was no significant difference in body weight between normal control and high dose treated groups (Figure 1).

**Effects of *Persea americana* on Fasting Serum Glucose Level**

Before treatment, the fasting serum glucose levels were significantly increased in all diabetic induced rats compared with normal control ($p < 0.05$). The mean value of fasting serum glucose was significantly reduced in rats treated with high dose of *Persea americana* on 4th ($p = 0.036$) and 6th week ($p =0.012$) compared with diabetic control group. Statistically significant decrease in serum glucose was also observed in moderate dose *Persea americana* juice treated group after the sixth week of treatment as compared with diabetic control group ($p = 0.02$). Metformin treated group showed significant reduction in fasting serum glucose on the 2nd ($p = 0.044$), 4th ($p = 0.021$) and 6th ($p = 0.013$) weeks of treatment, respectively compared with diabetic control group (Figure 2).

**Effects of *Persea americana* on Lipid Profile**

After the induction of diabetes and subsequent treatment with *Persea americana* juice, the mean values of TC ($p = 0.006$) and LDL-C ($p = 0.007$) in high dose treated diabetic induced rats were significantly reduced when compared with the mean values in the diabetic control group. In metformin treated group, the mean values of serum TC ($p = 0.003$) and LDL-C ($p = 0.006$) were significantly decreased compared with that of the diabetic control group. The mean values of TC ($p = 0.002$) and LDL-C ($p = 0.004$) in diabetic control group were significantly increased compared with that of the normal control group. Interestingly, there was no significant difference in mean values of TC and LDL-C in moderate and high dose *Persea americana* juice, and metformin treated groups when compared to normal control group. The mean value of fasting serum HDL-C was decreased in diabetic control rats, compared to normal control group ($p = 0.002$). On the other hand, the mean value of HDL-C was significantly increased in moderate ($p = 0.046$) and high ($p = 0.034$) doses of *Persea americana* and metformin ($p = 0.014$) treated groups as compared with diabetic control group. No significant difference was found in mean HDL-C level among the normal control, metformin control and high dose treated groups. The mean value of TG did not show any significant difference among all the study groups ($p > 0.05$), (Table 2).

**Discussion**

*Persea americana* is a fruit used as human food and in treating different diseases. In the present study, *Persea americana juice* was used to treat high fat diet and low dose STZ induced T2DM in male albino Wistar rats for six
weeks. The effect of *Persea americana* on food consumption, body weight, fasting blood glucose, lipid profile, total protein and creatinine was investigated in the diabetic rats.

In this study, food intake was higher in diabetic control group compared with in normal control group. It was also observed that the food consumption in high dose and moderate dose *Persea americana* juice treated groups of rats was lower than in diabetic control group. In addition, the pellet intake was reduced in the high dose treated group when compared with pellet intake in metformin treated group. The appetite decreasing of effect of *Persea americana* fruit juice is due to the presence of dietary fiber and fruit oil matrix, which acts by slowing gastric emptying and increasing early satiety in the rats (32, 33).

Slight body weight loss was observed in HFD and low dose STZ-induced diabetic rats following oral administration of both *Persea americana* fruit juice and metformin. In diabetic rats, decreased body weight may be due to an excessive breakdown of tissue proteins and lipid to provide energy as the body cannot use carbohydrate due to insulin insufficiency (34). The improvement in body weight seen in diabetic rats treated with *Persea americana* juice is most probably due to an improved metabolic activity that makes the body system more capable of maintaining blood glucose homeostasis (35). Similarly, 7mg/Kg of metformin treated rats gained body weight when compared with the diabetic group after six weeks of the treatment. However, the effect of metformin was less compared with that of *Persea americana* juice in normalizing body weight. The study done by Duerta *et al.* also reported that the β- sitosterol found in *Persea americana* showed body weight loss activity by reducing compulsive eating and fat accumulation in the abdominal region (36). The bioactive compounds found in *Persea americana* fruit juice may help in suppressing free radicals generation due to hyperglycemia and control muscle over wasting that resulted from glycemic control in treated diabetic rats, and ultimately lead to normalize the level of body weight (37).

In the first week of the experiment, fasting blood glucose concentration was elevated in all diabetic induced rats compared with normal control rats. This increase in fasting blood glucose concentration is an important characteristic feature of T2DM. However, for diabetic rats that received *Persea americana* juice, their fasting blood glucose was non-significantly reduced in the second week of the experiment. The fasting blood glucose level was significantly decreased on fourth and sixth weeks of the experiment in rats treated with moderate and high dose of *Persea americana* pulp juice when compared with glucose level of diabetic control rats. These results agree with Rao and Adinew’s results that reported albino Wistar rats received ethanolic extract of *Persea americana* fruit 300 mg/Kg/day, orally for 4 weeks, showed a decrease in the fasting blood glucose level, glycosylated hemoglobin, blood urea, and serum creatinine (35). Similar finding was also reported by Thenmozhi *et al.* in which treatment of Sprague Dawley rats with n-hexane fraction from hydromethanolic (2:3) extract of *Persea americana* fruit 30mg/Kg orally for 8 weeks showed decrease in fasting blood glucose level (38). A randomized clinical trials study done by Sabate *et al.* on 26 healthy overweight individuals also revealed that consumption of half avocado significantly reduced the blood insulin and glucagon-like peptide-1 levels (39). Moreover, the results of Wien *et al.* investigation on healthy overweight adults showed that avocado in lunch meal attenuated rise in postprandial blood insulin levels 30 min after start of the lunch meal and diminished the desire to eat compared with the avocado-free control group (33). On the other hand, low dose *Persea americana juice* did not cause significant change in fasting blood glucose throughout six weeks of the treatment, but decreased the levels to some extent.

The antihyperglycemic effect of avocado fruits may be related to insulin mimetic or stimulatory effect and its ability to stimulate the remaining pancreatic β- cells in animal models, making them able to secrete more insulin (35). The phytochemicals like flavonoids, saponins, tannins and alkaloids found in avocado act as anti-oxidants
and contain insulin stimulating substances such as insulin receptor substrate, glycogen synthase and glucose
dependent insulotropic polypeptide. *Persea americana* could decrease glucose level by increasing insulin secretion
or peripheral glucose utilization in the gut of normal treated rats (40). The D - manno heptulose found in *Persea
americana* may also be responsible for hypoglycemic effect by decreasing the rate of glycolysis via hexokinase
inhibition and weight control via appetite reduction.

In metformin treated group, the fasting blood glucose is significantly reduced starting from second week of the
experiment when compared with diabetic control group. Metformin reduces hyperglycemia by reducing
 gluconeogenesis, increasing insulin receptor sensitivity, especially in muscle cells, and decreasing glucose uptake
in the intestine (41-43). On the sixth week, no significant difference was found in fasting glucose levels among rats
 treated with moderate and high dose of *Persea americana* juice and metformin.

In addition to its anti-hyperglycemic effect, *Persea americana* fruit juice also showed the ability to alter lipid profile
(TC, LDL-C -C, TG, and HDL-C -C) levels in diabetic albino Wistar rats. The abnormally high concentration of serum
lipids in diabetes is mainly due to the increase in the mobilization of free fatty acids from the peripheral depots as
 insulin inhibits the hormone sensitive lipase. In our study, there was a significant increase in the serum TC and
 LDL-C levels in diabetic rats as compared with normal control rats. The elevated TG level in diabetic rats might be
due to the consequence of increased synthesis of triglyceride rich lipoprotein particles (VLDL-C) in the liver and
diminished catabolism. Since insulin has a potent inhibitory effect on lipolysis in the adipocytes, insulin deficiency
is associated with excess lipolysis and increased influx of free fatty acids to the liver (44). The increase in LDL-C
and VLDL-C levels in the HFD/low dose STZ induced diabetic rats might also be due to over production of LDL-C
and VLDL-C by the liver through stimulation of hepatic triglyceride synthesis as a result of free fatty acid influx.
The increased pool of triacylglycerol-rich lipoproteins, mainly VLDL-C1 observed in type 2 diabetes promotes CETP-
mediated triacylglycerol enrichment of HDL-C particles, and as a consequence enhances HDL-C catabolism, while
depleting them from cholesteryl esters, thus decreasing HDL-C cholesterol level (45).

Administration of high dose of *Persea americana* fruit juice decreased the mean serum TC and LDL-C levels in
HFD and low STZ induced diabetic rats compared with diabetic control group. Our results agree with of Pahua-
Ramos et al.’s results in which administration of reduced-calorie avocado paste 2 g/Kg/day for 7 weeks showed a
significant reduction in TC, LDL-C-C and increased insulin sensitivity in high cholesterol and fructose diet fed rats
(46). Similar in a study done by Elbadrawy and Shelbaya, administration of hydro-alcoholic extract of avocado130
and 150 mg/Kg/day administrated via stomach tube for 8 weeks showed a significant reduction in serum
cholesterol, LDL-C-C, and VLDL-C-C, while, the serum level of HDL-C-C was enhanced in HCD rats (47). In addition,
in study done by Al-Dosari, oral administration of *Persea americana* pulp 1 and 2 ml/rat/day for 10 weeks showed a
significant decrease in serum cholesterol, LDL-C-C, VLDL-C-C and TG levels (48). The LDL-C and TC reducing
effect of *Persea americana* fruit pulp juice is due to its phytosterols, phytostanols and dietary fiber, which help
reduce cholesterol reabsorption in the intestine and promoting fecal cholesterol excretion, which in turn reduces the
level of LDL-C in plasma, increasing the amount of cholesterol excreted from the body and decrease in hepatic
cholesterol synthesis (49, 50).

In addition, the soluble dietary fiber found in avocado juice pulp may decrease the LDL-C and TC levels by binding
to bile acid and alters micelle formation, and results in decreased micelle absorption in the small intestine.
Moreover, the extract of avocado fruit inhibits the action of acetyl-CoA carboxylase, a key enzyme catalyzing the
committed in fatty acid synthesis (51). Treating diabetic rats with metformin decreased the serum TC and LDL-C at
the end of the experiment (6th weeks). Metformin increases insulin sensitivity by decreasing the rate of lipolysis there by slowing the conversion of FFA to lipoprotein precursors in the liver.

Interestingly, the mean value of HDL-C was significantly increased in in diabetic rats treated with double and triple doses of Persea americana fruit juice when compared with diabetic control rats. This result is in line with the result of Elbadrawy and Shelbaya, in which administration of hydroalcoholic extract of avocado pulp 150 mg/Kg for 8 weeks increased HDL-C in HCD rats (47). The possible mechanism by which avocado enhances HDL-C serum level may be by regulating the hydrolysis of certain lipoproteins and their selective uptake, and metabolism by different tissues due to presence of tocopherols, phytosterols and polyphenols in the fruit. Avocado also modifies the structure of the HDL-C lipoprotein by increasing paraoxonase-1 enzyme activity, which is responsible for the hydrolysis of lipid hydroperoxides (52). In the same way, the HDL-C cholesterol level was significantly increased in diabetic rats treated with metformin drug compared with in diabetic control rats.

On the other hand, no dose of avocado showed significant effect on serum TG level in all treatment groups compared to diabetic control group (p > 0.05). However, there was a decrease in mean value of serum TG after the treatment. This result is in agreement with Pieterses's, in which 200g/day of avocado substituted for 30 g of other mixed dietary fats for 6 weeks didn't significantly change the TG, HDL-C, LDL-C and TC levels in energy-restricted-diet volunteers (53). On the contrary to our study, study done by Shehata and Soltan revealed treatment of hypercholesteromic rat with 30% avocado fruit for 4-weeks reduced TG levels significantly (54). This difference might be due to the difference in extraction method used.

In T2DM, insulin resistance does not alter only glucose and lipid metabolism, but also protein metabolism. In the present study, the total protein level was reduced in diabetic rats relative to in normal control rats. Diabetes mellitus reduces total protein level by increasing muscle proteolysis, reducing protein synthesis and stimulating hepatic gluconeogenesis. Although the differences were not significant, treating diabetic rats with different doses of avocado fruit juice was found to improve the total protein concentration. The metformin treated group also did not show significant difference in protein level compared to diabetic control group. In diabetic rats, breaking down of liver and plasma protein enhances serum creatinine level. The administration of Persea americana fruit juice and metformin to diabetic rats decreased serum creatinine level insignificantly. This indicates that the effect of Persea americana in normalizing protein metabolism disturbance is comparable to that of metformin.

Conclusion

The present study revealed that the antihyperglycemic and antihyperlipidemic effect of Persea americana fruit juice in HFD/low dose STZ induced T2DM albino Wistar rats is a dose dependent. Particularly, high dose (1896 mg/Kg/day) of Persea americana juice significantly reduced pellet consumption than metformin. Similarly, Persea americana fruit juice showed the effect of normalizing body weight and reducing fasting blood glucose level. Treating diabetic rats with Persea americana juice (1264 mg/Kg, 1896mg/Kg/day) showed significant fasting blood glucose reduction on the 4th and 6th weeks. It was also found that Persea americana fruit pulp also has a potential reducing effect on LDL-C, TC and increasing effect on HDL-C in STZ and HFD induced diabetic albino rats. Overall, the findings of our study showed that Persea americana fruit pulp juice has the effect of normalizing metabolic disturbances of carbohydrate and lipid caused by T2DM and HFD, hence it may be helpful in reducing the risk of diabetic complications.

Declarations

Acknowledgment

We would like to express our earnest gratitude to Dilla University and Addis Ababa University for funding this research project. We are extremely grateful to the Department of Medical Biochemistry, Addis Ababa University, for its indispensable support and coordination in smooth running of this project.

Authors’ contributions

TG conceived and designed the study, conducted the experiment, analyzed and interpreted the data, and wrote the manuscript. SG and AT designed the study, analyzed and interpreted the data, and TOF assisted in study designing, conducting the experiment, data analysis and interpretation, and manuscript writing. All the authors read, commented on, and contributed to the submitted and revised manuscript.

Funding

The research was funded by Dilla University and Addis Ababa University. The funders had no role in designing the study, collection, analysis, and interpretation of data as well as in the writing of the manuscript.

Availability of data and materials

All necessary data and materials are included in this manuscript and supplementary data and materials related to the article can be obtained from the authors when necessary.
Competing interests

The authors declare that they have no competing interests.
