Abstract

A novel [ZrO2+BTB]^C nanocomposite was synthesized and prepared as a thin film using the Sol-Gel spin coating method. Different characterization techniques for [ZrO2+BTB]^C like FTIR, UV-Vis, and optical properties have been used. The resulted XRD and SEM data have been employed to study interface composites. The optimization was performed using DFT by *DMol^3* and *CASTEP* program. The chemical structure was confirmed by spectroscopic and structural properties for [ZrO2-BTB]^C, XRD results showed the same crystal structure. Combined between experimental and TDD-DFT data, the average crystallite size and composite interface are 12.36 nm and orthorhombic symmetry (a= 7.38(5); b= 18.178(6); c= 26.10(3) Å and a= b= g= 90º) with space group (P6$_1$) for [ZrO2+BTB]^C, respectively. Furthermore. While the computed by DFT are 2.897 eV and 2.492 eV for as-isolated crystals of [BTB]^{TF} and [ZrO2+BTB]^C, respectively. Both [BTB]^{TF} and [ZrO2+BTB]^C thin films have direct allowed transitions. In addition, the optoelectrical parameters have been calculated for [BTB]^{TF} and [ZrO2+BTB]^C films such as refractive index, extinction coefficient, dielectric constant, and optical conductivity. The simulated values obtained by CATSTEP for the optical parameters of [ZrO2+BTB]^C are in good agreement with the experimental values. The [ZrO2+BTB]^C presents a good candidate for optoelectronics and solar cell applications.

Keywords: Nanocomposite [ZrO2+BTB]^C, XRD, DFT, thin films, optical properties

1. Introduction

The applications of dye composites in industries have been enhanced quickly due to their unique properties, such as light-in-weight, high stiffness, and high strength. [1-2]. Bromothymol blue (C$_{27}$H$_{28}$Br$_2$O$_5$S) (sometimes known as bromothymol sulfone phthalein, and BTB) is one of the promising candidates for state-of-the-art organic semiconductors, valid for various optoelectronic devices [3]. It is regularly used in applications that need measuring substances that would have a relatively neutral pH $\cong$ **7** [4,5]. Sulfone phthalein dyes are an essential pH indicator class for some applications in modern sensors [6-7]. For this goal, the sol-gel process has been successfully employed due to its singular versatility and the following characteristics: optic transparency, mechanic stability, chemical resistance,

---

∗Corresponding authors email: Ahmed F. Al-Hossainy (ahmed73chem@scinv.au.edu.eg)

and flexibility of sensor morphological configurations [8–10]. Therefore, these materials have potential applications in the pharmaceutical, food, and chemical industries [11, 12]. Once again, the molecular chemical reactivity of the dye molecules was investigated using DFT-based reactivity descriptors, electrophilicity index (A), chemical potential (µ), and chemical hardness (A) values were approximated in terms of molecular orbital energy, HOMO and LUMO frontier values [13]. A TD-DFT investigation of ground and excited-state properties in indoline dyes used for dye-sensitized solar cells, the ground and excited-state properties of three indoline dyes, namely D102, D131, and D149, specially designed for dye-sensitized solar cell applications have been studied by the means of density functional theory (DFT) and time-dependent DFT (TD-DFT) and compared with experimental absorption and fluorescence spectra [14].

Sulfonphthaleine dyes are an essential pH indicator class for certain applications in new sensors. A theoretical analysis to elucidate the impact of physical factors on the sulfonphthalein dyes halochromic behavior. Sulfonphthaleine dyes are phenol red, cresol red, bromophenol blue, and consideration are given to physical factors such as temperature, strain, solvent dielectric constant, and the form of constituent atoms isotope. Meanwhile, variations in pH of indicator color change, i.e. pH, are studied with the indicators' physical factors in the acid-base equilibrium. These findings show the significance of physical factors on the halochromic activity of colorants for further study and the production of pH sensors [15].

At the same time, environmentally friendly nano regime materials were developed for the past few years with the aim of low-cost production using simple green technologies. Nano zirconia $[ZrO_2]^{NPs}$ are widely used in various photocatalytic, piezoelectric applications, as a catalyst in various organic reactions [16] and industries for ceramics, dental, and optical coatings [17,18]. The cytotoxic activity of nanoparticles mainly depends on its size and shape [19, 20]. Various chemical methods such as the solvothermal method, hydrothermal method [21-25], aqueous precipitation method [26], sol-gel method [27-29], thermal decomposition methods [30-32] and pyrolysis of zirconium oxychloride salt organic precursors have been applied to prepare ZrO_2 NPs [33]. These methods are more effective for controlling the shape and size of nanoparticles but often results in the formation of mixed crystal phases [34-36]. However, all these methods require high temperature, costly, and environmentally hazardous chemical precursors during synthesis processes [37-38].

In this work, a novel synthesizes $[ZrO_2+BTB]^C$ to study the structural and optical properties of the fabricated nanocomposite thin films has been carried out. Also, study the molecular structure of $[ZrO_2+BTB]^C$ using FTIR and molecular electrostatic potential (MEP) techniques. Also, the configuration and morphology description of the $[ZrO_2+BTB]^C$ using XRD and SEM techniques will be

studied. Finally, the optical properties of the fabricated film have been carried out. Simulated measurements of the optical properties were also conducted for $[ZrO_2+BTB]^C$ as-deposited films by CATSTEP in the DFT method.

2. Experimental tools and measurements:

2.1 Materials

The list of chemicals used in conducting the current experiments is presented in Table 1. All chemicals were utilized as received without supplementary refinement.

Table 1. List of chemicals used and their molecular formulas

Chemical	Molecular formula	Supplier
Bromothymol blue (BTB)	$C_{27}H_{28}Br_2O_5S$	(Aldrich Chemical Co. Ltd)
Zirconium nitrate	$Zr(NO_3)_4$	BDH
Oxalic Acid	$C_2H_2O_4.2H_2O$	LOBA Chemie, India
Ethanol	C_2H_5OH	Aldrich
Anhydrous dimethyl formaldehyde (DMF)	C_3H_7NO	Merck
Dimethyl sulfoxide	C_2H_6SO	Merck
Hydrochloric and Hydrofluoric acid	HCl and HF	Sigma &Aldrich
Single crystal of p-Si	p-type	
Perchloric acid) and Nitric acid	$HClO_4$ and HNO_3	Merck

2.2 Fabrication of $[ZrO_2-BTB]^C$

To synthesize zirconium nanoparticles $[ZnO_2]^{NPs}$, 1.0 M solution was prepared by dissolving 15.43 g of high purity zirconium (IV) nitrate in 100 ml double-distilled (DD) water under magnetic stirring. Another 1.5M solution was prepared by dissolving 18.91 g of high purity oxalic acid in 100 ml DD water. This second solution was added into the first one and the stirring continued for 2 h at 50 °C. The mixed solution was aged for 10 h at room temperature (RT) then stirred at 80 °C for 30 min [39]. 0.5 g BTB was dissolved in 25 ml DD water/ethanol (50:50 %) at 50 °C and magnetic stirring for 1 h till the complete dissolution of BTB. The homogenous BTB solution was doped with the prepared sol-gel $[ZrO_2]^{NPs}$ at ratio $W = 0.5\%\,wt.$ using the equation: $W(wt.\%) = \left[\frac{w_{ZrO2\,NPs}}{w_{BTB}+w_{ZrO2\,NPs}}\right]x100$ where $w_{ZnO2\,NPs}$ and w_{BTB} is the $[ZrO_2]^{NPs}$ and BTB weights, respectively. Finally, the solutions were cast into cleaned glass Petri dishes and placed in an oven to dry at 60 °C for 24 h in air. The homogenous solution was peeled off from the Petri dishes and care was taken to obtain the polymer thin film $[ZrO_2-BTB]^C$ of uniform thickness. Finally, $[ZrO_2-BTB]^C$ was kept in zipper bags to prevent humidity influence.

2.3 Characterization

Characterization methods and typical conditions are listed in Table 2.

Table 2. List of characterization methods.

Characterization method	Model used and specifications
FT-IR	Perkin-Elmer FT-IR type 1650 spectrophotometer (wavelength range 4000 – 200 cm^{-1}).
XRD	Philips X-ray diffractometer (model X'pert) with monochromatic Cu Kα radiation operated at 40 kV and 25 mA.
SEM	Scanning Electron Microscopy (SEM; Inspect S, FEI, Holland), operated at an accelerating voltage of 3.0 kV
Thermal Evaporator	Edwards type E 306 A, England
Film thickness	Model FTM4. Edwards, England
UV	SHIMADZU UV-3101 UV–vis–NIR pc.

3. Results and discussions

Scheme 1 summarizes the reaction of [BTB] ethanolic solution with [ZrO$_2$]^{NPs} to form [ZrO$_2$+BTB]^C compound. Mechanism of reaction between [BTB] in (50:50 v/v) aqueous/ethanolic solution with [ZrO$_2$]^{NPs} by using a spin coating (Sol-Gel Method) for the formation and decomposition [40]. The reaction of [ZrO$_2$]^{NPs} with BTB is shown in Scheme 1 to form the novel [ZrO$_2$+BTB]^C nanocomposite.

3.1. Fourier Transform Infrared Spectroscopy (FT-IR)

FT-IR reveals chemical changes to the structure of the dye and nanocomposite. Fig.1 and Fig. 2 show the experimental and simulation IR spectrum of [BTB] and [ZrO$_2$+BTB]^C, respectively [41]. In the experimental spectrum (Fig.1) for both [BTB] and [ZrO$_2$+BTB]^C, a strong absorption band was detected at 3400 cm^{-1} which can be attributed to stretching hydroxide group in BTB dye ν(OH) and intra- water molecular vibration (ν$_{OH}$) for both [BTB] and [ZrO$_2$+BTB]^C, respectively [42-43]. The bands at 2960 cm^{-1} and 2868 cm^{-1} due to (ν$_{C-H}$) stretching of alkane in benzene ring for both [BTB] and [ZrO$_2$+BTB]^C. Bands at 1605 cm^{-1} and 1472 cm^{-1} were allocated to C-H bond stretching and bending vibrations (ν$_{CH}$ and δ$_{CH}$) for both [BTB] and [ZrO$_2$+BTB]^C, respectively [44-45]. In contrast, absorption bands around 1402 cm^{-1}, 1193, and 1160 cm^{-1}, were attributed to antisymmetric ν(o=S=O) for both [BTB] and

4

[ZrO$_2$+BTB]^C. Moreover, the bending vibration of the ether (glycosidic) linkage δ (S-O-C) was designated by a strong peak at 1040 cm^{-1} [46]. The [ZrO$_2$+BTB]^C spectrum (Blue color) presents besides the above bonds a peak that is not found in that of [BTB], particularly at 3480 cm^{-1} is due to Zr-OH$_2$ rocking of water. And also, the spectrum of the ZrO$_2$+BTB]^C exhibit additional FTIR strong bands at 570 cm^{-1}, 543 cm^{-1} and 464 cm^{-1} assigned to ν (M-O) modes [47].
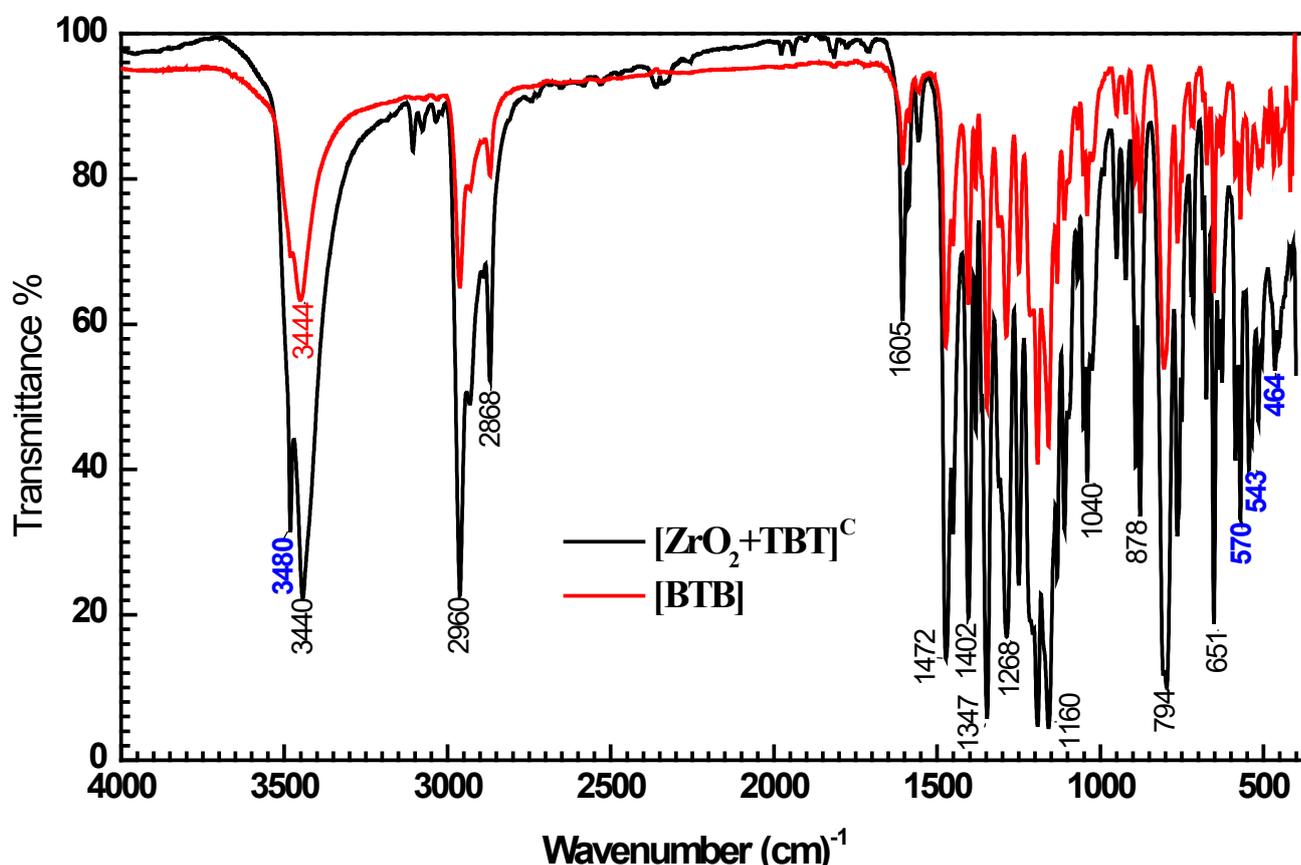

Fig. 1. The FTIR spectra experimental data of [BTB] and [ZrO$_2$+BTB]^C.

The *Gaussian simulation* spectra for both [BTB] and [ZrO$_2$+BTB]^C have been studied in an isolated state. A strong absorption bands were detected at range 3600 cm^{-1} to 3850 cm^{-1} which can be attributed to intra- water molecular vibration (ν$_{OH}$) for both [BTB] and [ZrO$_2$+BTB]^C. The bands at range 2900 – 3100 cm^{-1} were allocated to C-H bond stretching and bending vibrations (ν$_{CH}$ and δ$_{CH}$) for both [BTB] and [ZrO$_2$+BTB]^C. this vibration of ν$_{CH}$ and δ$_{CH}$ also appear at range 1500 – 1600 cm^{-1}. In contrast, the absorption bands around at 1200-1300 cm^{-1} were attributed to antisymmetric (ν$_{C-S-O}$) for both [BTB] and [ZrO$_2$+BTB]^C. The [ZrO$_2$+BTB]^C spectrum presents besides the in above bond peaks that are not found in that of [BTB], particularly at 549 cm^{-1} 452 cm^{-1} which are allocated to metal oxide (Zr-O) [48-49].
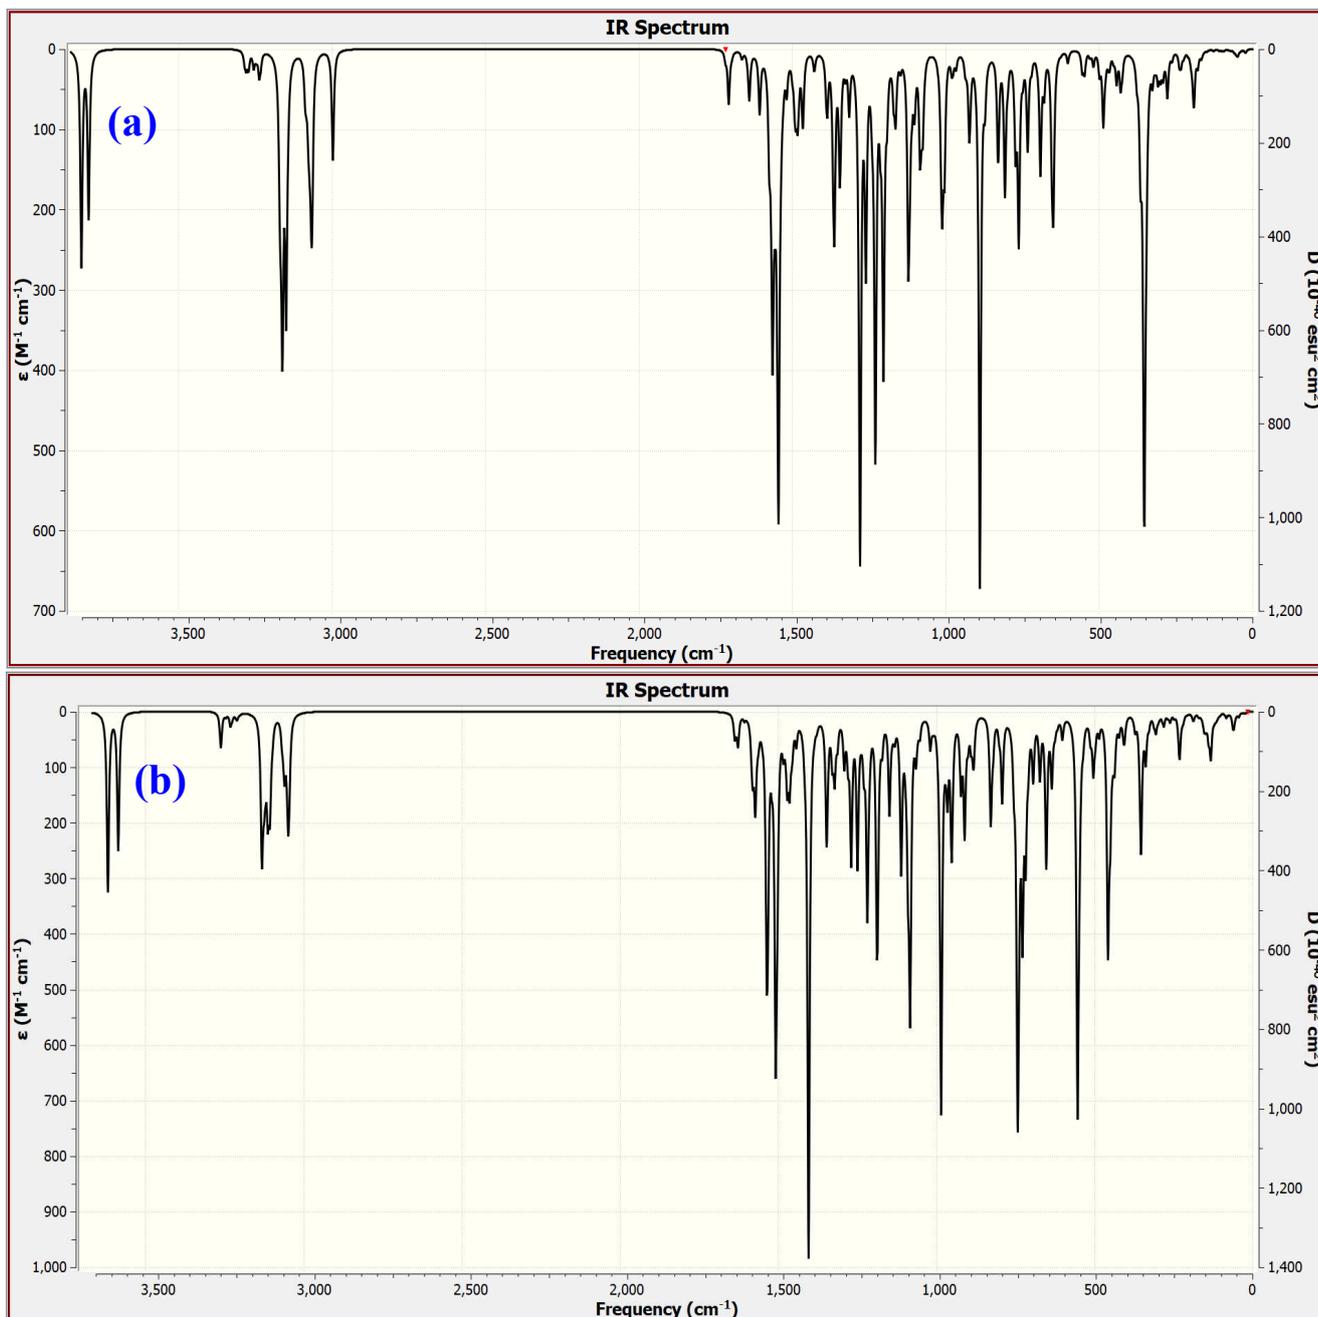

Fig. 2(a-b). The FTIR spectra *Gaussian data* of [BTB] and [ZrO$_2$+BTB]^C.

It has been concluded that when the comparison between FTIR experimental data for [BTB] and [ZrO$_2$+BTB]^C as thin films (Fig. 1) and IR Gaussian simulation for [BTB] and [ZrO$_2$+BTB]^C as isolated state or gas state (Fig. 2(a-b)) that has a good agreement [50]. These agreements in peak intensities and locations confirmed the formation of the predicted [ZrO$_2$+BTB]^C structure in Scheme 1.

3.2. XRD

The X-ray powder diffraction analysis (XRD) is used to identify atomic configurations of orientation and crystalline phases: structure, target direction, change in order-disorder, thermal expansions, and thickness measurements for thin films and multilayer [51-52]. In an XRD study, a diffractogram indicates

6

the frequency according to the angle of diffraction. Fig. 3 shows the experimental XRD diffractograms for both $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$. XRD patterns of $[BTB]^{TF}$ polymer show distinguished peaks with *hkl* at (101) and (200) as semicrystalline powder behavior. However, the XRD pattern of $[ZrO_2]^{NPs}$ illustrates several peaks in the range of 4º < 2θ < 80 º with *hkl* at (250), (311), (241) and ($\overline{7}$12). The high crystallinity and the high order within the sample were identified. The specific distributed signals and the position of the peaks (2θ) show also the structure of the organic compound. Finally, the highest peaks in this pattern with *hkl* can be observed at (101), (200), (250), (311), (241) and ($\overline{7}$12) corresponding to the crystalline aspect of $[ZrO_2+BTB]^C$ nanocomposite.

The Bragg diffraction proves that both $[BTB]^{TF}$, $[ZrO_2]^{NPs,}$ and $[ZrO_2+BTB]^C$ have orthorhombic symmetry with different crystalline structure parameters [53-54] tabulated in Table 3. The main cause of this crystallization is probably the introduction of $[ZrO_2]^{NPs}$ to $[BTB]^{TF}$. The machine error, root mean square deviation (rmse), and orthodromic cell volume of $[BTB]^{TF}$, $[ZrO_2]^{NPs,}$ and $[ZrO_2+BTB]^C$ lattices are illustrated in Table 3. The averaged-spacing distance between atomic layers is 2.454 Å, 2.525 Å, and 2.878 Å for $[BTB]^{TF}$, $[ZrO_2]^{NPs,}$ and $[ZrO_2+BTB]^C$, respectively. Table 3 provides peak data of $[BTB]^{TF}$, $[ZrO_2]^{NPs,}$ and $[ZrO_2+BTB]^C$ using the Bragg equation while the d-spacing for the strongest crystalline signal is calculated with the Debye – Scherrer equation. This equation is $FWHM(2\theta) = (b\lambda/Dcos\theta)$ in terms of 2θ, where *FWHM* is the full width of the peak, 2θ is the scattering angle in radians, λ is the wavelength, *b* is a constant, which normally takes a value between 0.89 and 0.94 depending on the function used to fit the peak, and *D* is the dimension of the crystallites as if they were cubes, monodisperse in size. Therefore, for different reflections and different crystallite shapes, the interpretation of *D* must be treated with some care. For polydisperse systems, *D* is a measure of the volume-averaged crystallite size. Thus, the $[BTB]^{TF}$, $[ZrO_2]^{NPs}$ and $[ZrO_2+BTB]^C$ average crystallite size are $D_{av}=31.63$ nm, $D_{av}=23.74$ nm and $D_{av}=18.21$ nm, respectively. This decrease in the average crystallite size of $[ZrO_2+BTB]^C$ indicates a relatively low graphitization degree even after treatment and correlates. The simulation data conducted using *Crystal Sleuth software* (Program REFINE Version 3.0) Kurt Barthelme's and Bob Downs) and material studio software (PMP predict) is in great compliance with experimental XRD patterns (Fig. 4) [55].
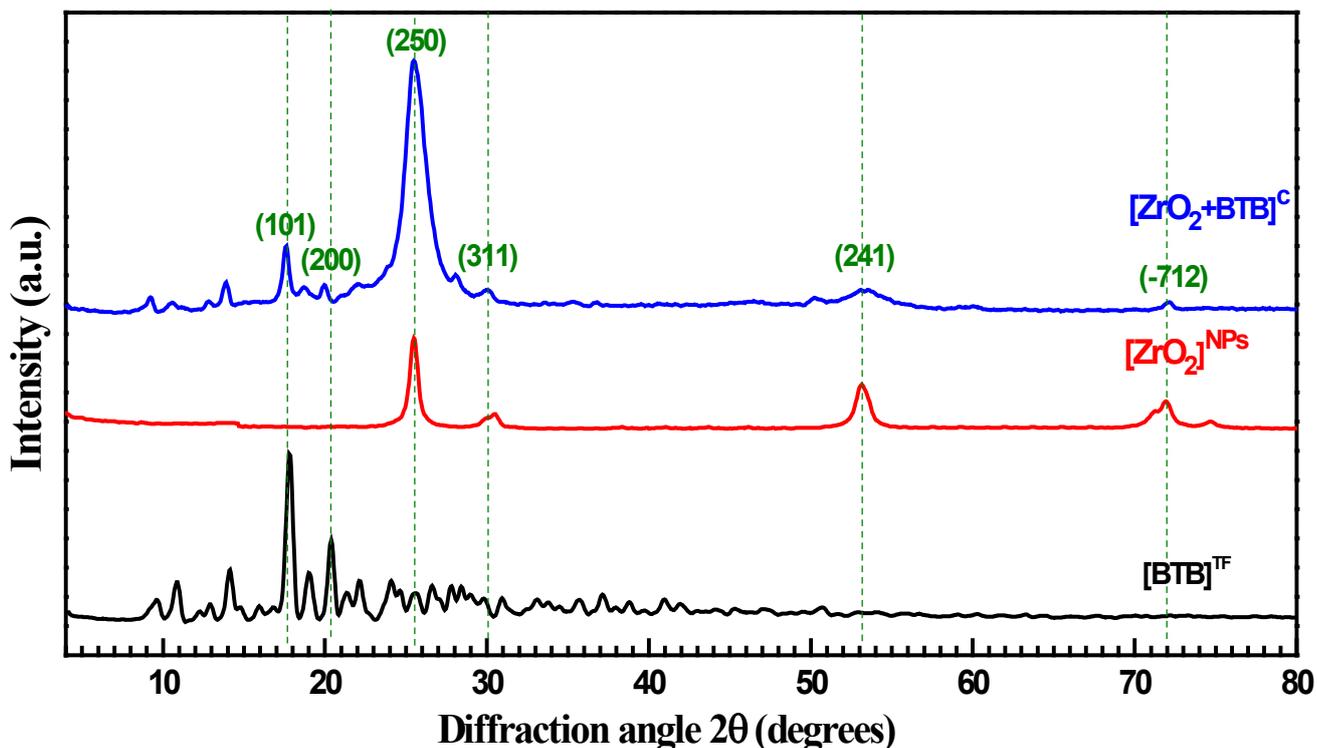

Fig. 3. Experimental XRD pattern of [BTB]^{TF}, [ZrO$_2$]^{NPs} and [ZrO$_2$+ BTB]^c

Using the *Materials Studio* and Crystal *Sleuth software* results, the unit cell lattice parameters (a, b, c, α, β and γ) and space group (P6$_1$) of [BTB]^{TF}, [ZrO$_2$]^{NPs,} and [ZrO$_2$+ BTB]^c are tabulated in Table 3. The first step in the simulation was the preparation of the [BTB]^{TF} and [ZrO$_2$+ BTB]^c layers. The free ligand [BTB]^{TF} and [ZrO$_2$]^{NPs} layers of [ZrO$_2$+ BTB]^c were constructed using atomic coordinates from the previously reported crystal structure of the *American Mineralogist Crystal Structure Database* [56-57], whose X-ray crystal structure had been refined in an orthorhombic. The differences are not significant when one considers that the reported uncertainties are those of the fit, not including any effects arising from systematic errors.
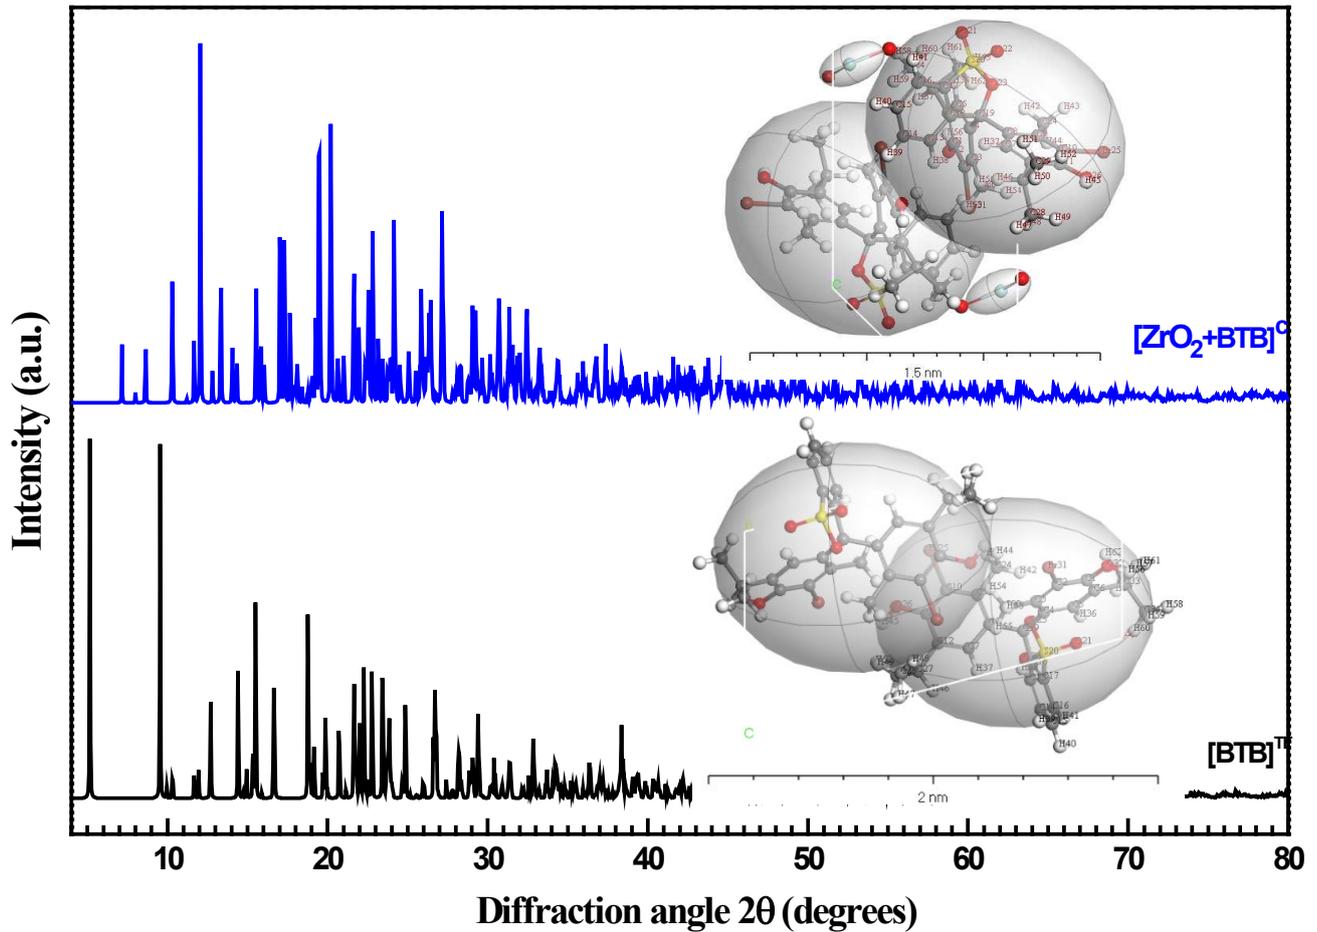

Fig. 4. Simulation XRD pattern of [BTB]^{TF} and [ZrO$_2$+ BTB]^c by using Material Studio.

3.3. SEM

Quantitative structural characterization was carried out using SEM images of the fabricated nanocomposite materials. Topographic features of both [BTB]^{TF} and [ZrO$_2$+ BTB]^c as-deposited thin films (150 nm thickness), by using SEM images, were studied as shown in Fig. 5(a-b). As seen in Fig. 5a, the as-obtained films of [BTB]^{TF} prepared by the Sol-Gel method aggregated easily and formed nano spherical aggregates. The average calculated value of particle size by SEM images for [BTB]^{TF} spherical films is 35 ± 5 nm, which coincides with that obtained by XRD measurements. On the other hand, Fig. 5b displays SEM images of [ZrO$_2$+ BTB]^c as-deposited thin films. Image of [ZrO$_2$+ BTB]^c shows a one-dimensional morphological structure with arranged, densely packed fibrous nanowires (i.e, like rods shapes) or brush such as a uniform structure was grown. By using the image j software program, Fig. 5b shows a long-range uniformity of the nanowires with an average thickness of $\cong 0.45$ µm ± 15 nm and the length in the range $\cong 4.12$ µm ± 38 nm for.

A larger surface region is accorded by microfiber structures resulting from the synthesis of the nanocomposite thin films. The fabrication of [ZrO$_2$+ BTB]^c microfibers derives from a self-assembling process of co-[ZrO$_2$]^{NPs} – [BTB]^{TF} units, which contain π-type bonds. Clarification for the process of

9

self-assembling as reported by [58-61], which consider both the intermolecular $\pi \rightarrow \pi^*$ interactions with the hydrogen bonds linked between $[ZrO_2]^{NPs}$-$[BTB]^{TF}$ chains.

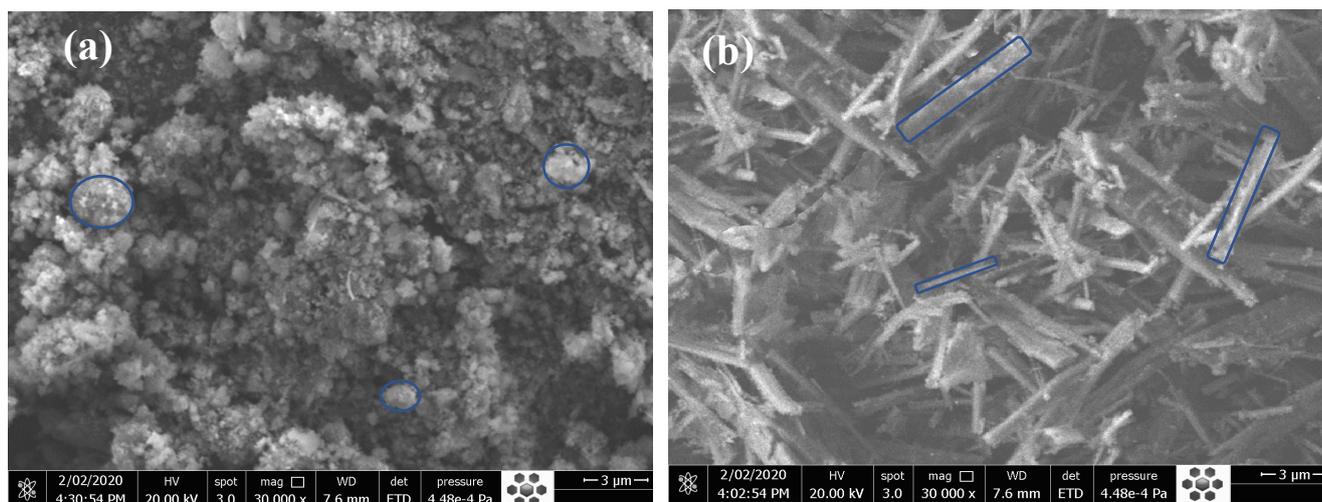

Fig. 5 Top view of the prepared $[BTB]^{TF}$ and $[ZrO_2+ BTB]^{C}$ thin films (150 nm) using the SEM technique.

3.4. Molecular electrostatic potential (MEP), electron density (ED) and Potential of [BTB] and $[ZrO_2+BTB]^{C}$.

The active location of MEP is displayed by a 3D illustration in Fig. 6(a) and Fig. 6(d) for [BTB] and $[ZrO_2+BTB]^{C}$, respectively. The blue color constitutes the propitious zone for the nucleophilic attack, while the propitious zone for electrophilic attacks is constituted by a red color. The potential range [P] of the matrix BTB and $[ZrO_2+BTB]^{C}$ in the isolated molecule and crystal models are $-6.553\times10^{-2} \geq[P]\geq 6.523\times10^{-2}$ and $-7.063\times10^{-2} \geq[P]\geq 7.063\times10^{-2}$, respectively, while the increase follows the order: red < brown < blue [62]. The blue color is the largest attraction, whereas the red color is a powerful repudiation. The diagram of the MEP reveals that nitrogen electronegative atoms reflect the regions of negative potential and hydrogen atoms have a positive potential [63]. The chemical and physical similarities of [BTB] and $[ZrO_2+BTB]^{C}$ have been investigated by utilizing the electron density and the electrostatic potential. The basic principle of DFT Fig. 6(a) and Fig. 6(d), the use of electron density as the essential factor to define the ground state of many-electron systems is further discussed for [BTB] and $[ZrO_2+BTB]^{C}$, respectively. The potential possible diagrams of [BTB] and $[ZrO_2+BTB]^{C}$ (Fig. 6(b) and Fig. 6(e)), the potential growth of [BTB] is shown to be lower than that of $[ZrO_2+BTB]^{C}$. This indicates an increased probability of electron transition in $[ZrO_2+BTB]^{C}$. The MEP has been used to describe the electrostatic potential depending on the constant electron density surface.
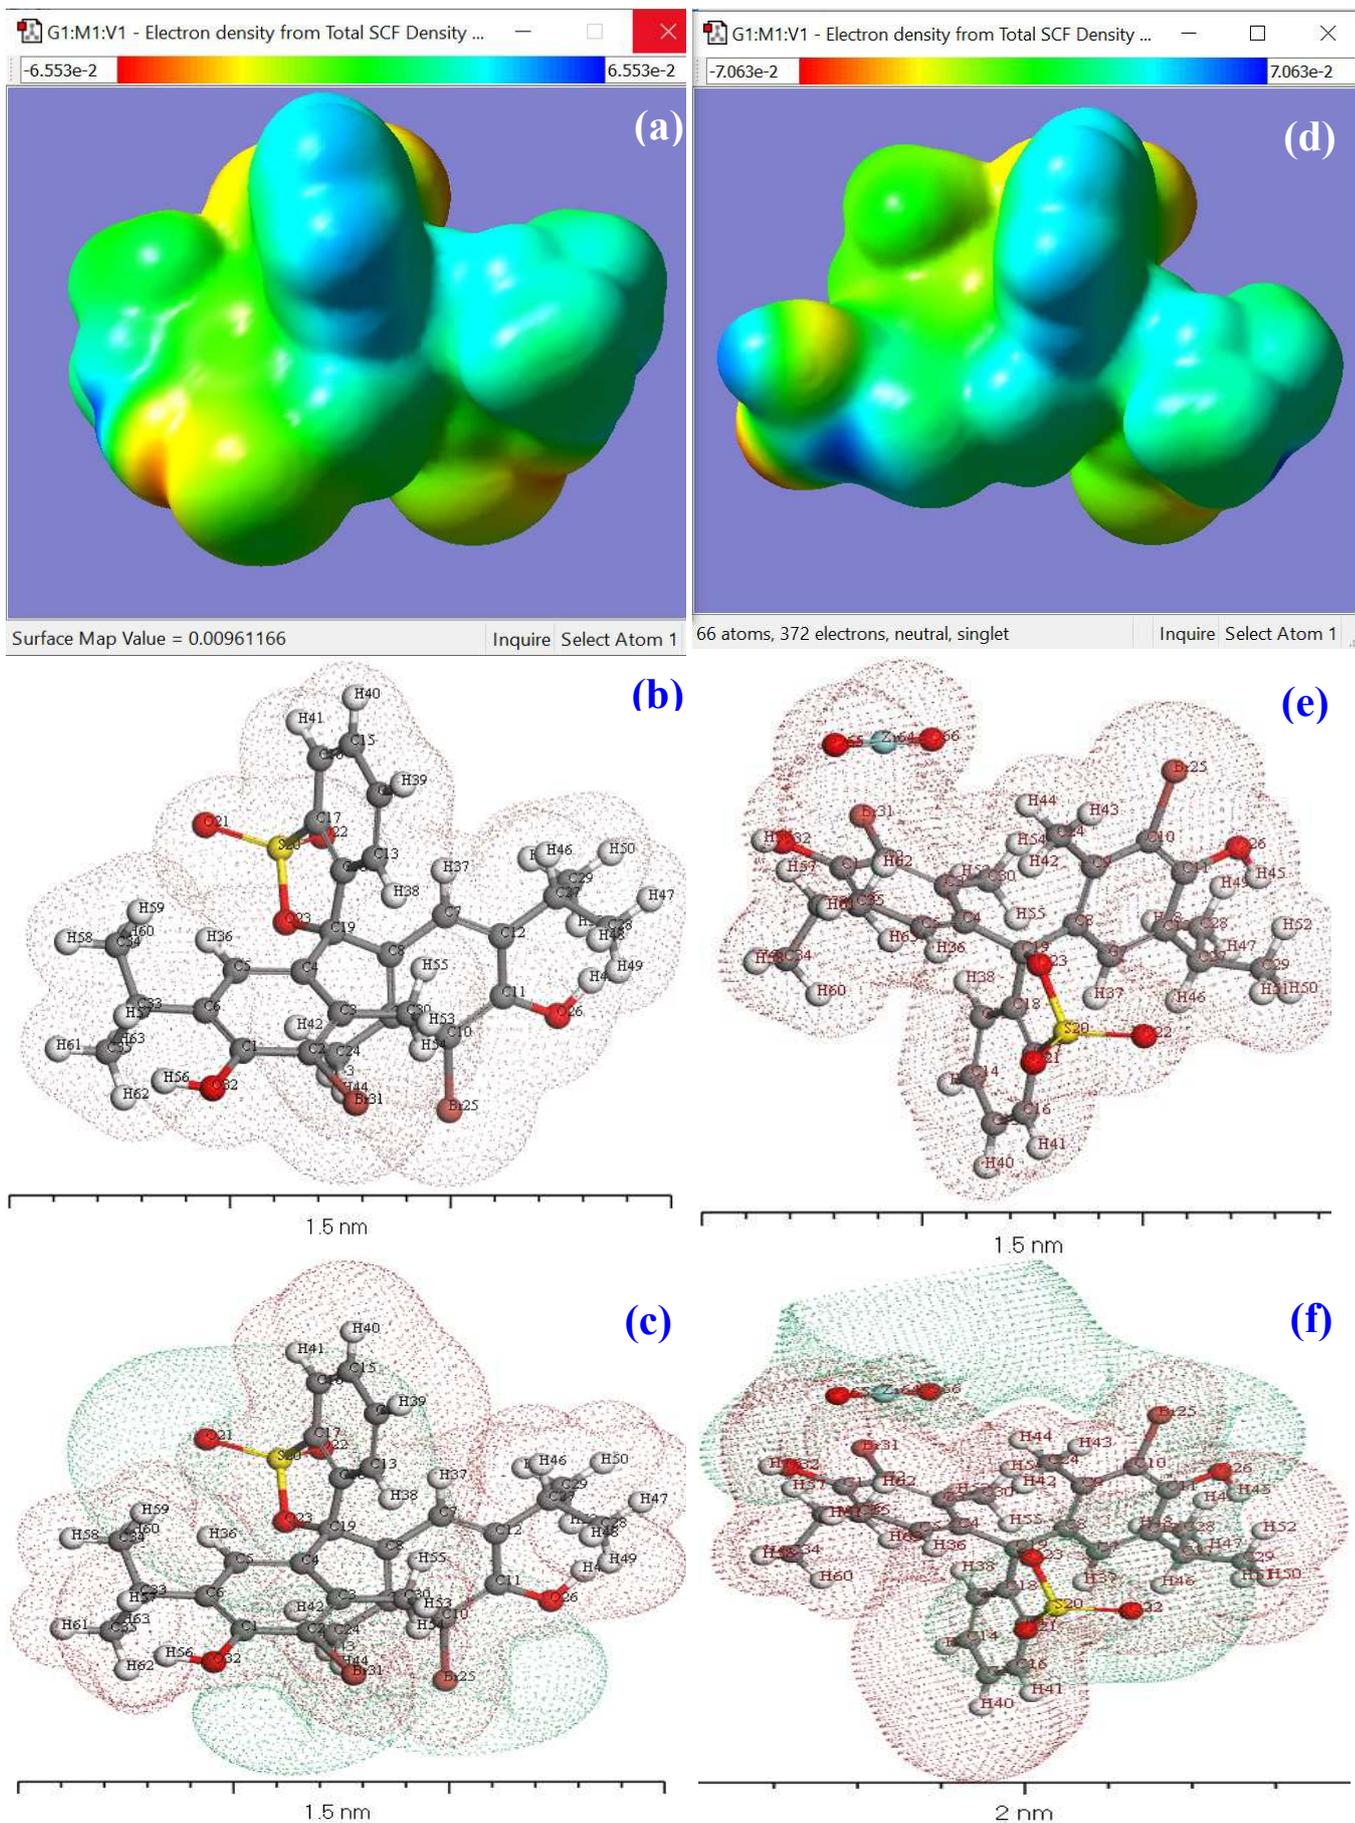

Fig. 6 a) MEP of [BTB]; b) Electron density of [BTB] ; c) Potential of [BTB], d) MEP of [ZrO$_2$+BTB]^C; e) Electron density of [ZrO$_2$+BTB]^C and e) Potential of [ZrO$_2$+BTB]^C by using DFT calculation in *material studio* and *Gaussian software* programs

3.5. Optical properties of both [BTB]^{TF} and [ZrO$_2$+BTB]^{C} thin films

UV–Vis spectroscopy indicates absorbent spectroscopy in this region of spectra. Since the atoms and molecules experience electronic transformations in the ultraviolet-visible region of the spectrum. Both bromothymol blue [BTB]^{TF} and [ZrO$_2$+BTB]^{C} thin films were more validated by UV-Vis absorption spectroscopy as shown in Fig. 7. The spectra measurements for [BTB]^{TF} and the hybrid [ZrO$_2$+BTB]^{C} were measured using a spectrophotometer at room temperature in the wavelength range as $250\ nm \le \lambda \le 700\ nm$. The spectra of all features of [BTB]^{TF} thin-film discover three bands of absorption at 280, 328, and 422nm, respectively. The band of $\lambda_{max} = 422\ nm$ is the maximum broadband (i.e, the core band of BTB) of a wavelength region ranged from $360\ nm <\lambda< 550\ nm$.

Also, Fig. 7 shows the UV-Vis absorption spectrum for the hybrid nanocomposite of [ZrO$_2$+BTB]C thin film. The spectrum is characterized by three band peaks, but with a double value of absorbance. This may be due to the ZrO$_2$ molecules. Since adding the ZrO$_2$ in the [BTB] dye matrix increases the peak strength. There is therefore a chemical reaction between the two components in the matrix, and the increase in absorption is due to the increase in the percentage of ZrO$_2$, which is the absorbing component.

Moreover, there are no shifts in first and second band peaks maximum wavelengths (i.e, λmax. are 280nm and 328 nm). While the third band peak has been divided into two sharp peaks with λmax equal to 416nm and 422nm, respectively. The three absorption peaks at about 280, 328, and 422 nm are attributed to the electrons transition from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital LUMO, which is related to $\pi \to \pi^*$ electronic transition for both [BTB]^{TF} and [ZrO$_2$+BTB]^{C} [64-68].
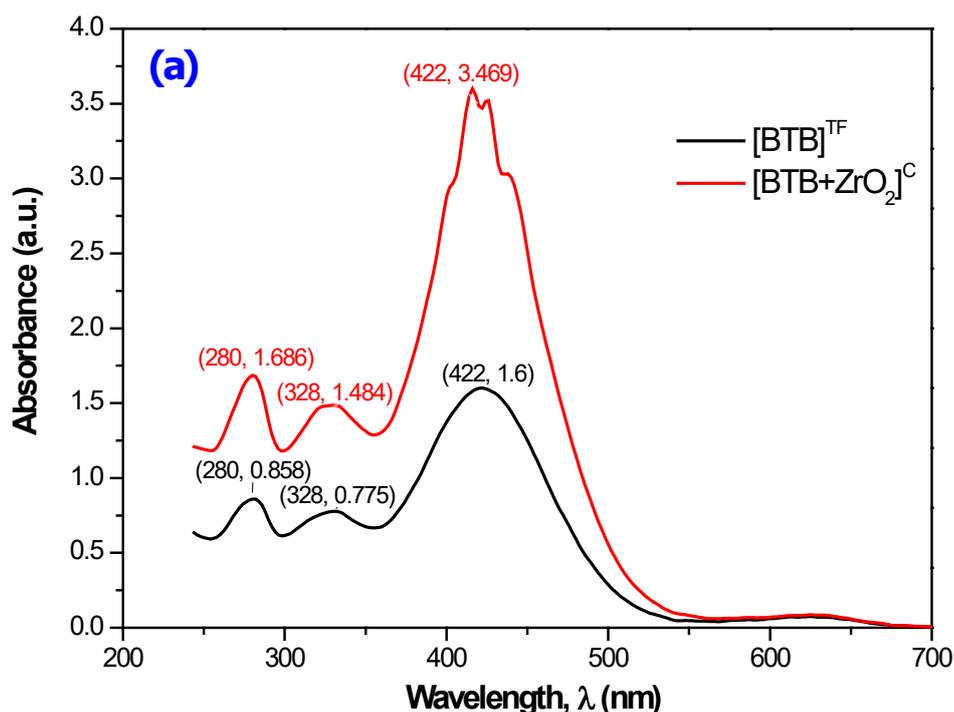

Fig.7 a) UV–vis absorption spectra of [BTB]^{TF} and [ZrO$_2$+BTB]^C

3.6 Energy gaps calculations by Tauc's and DFT simulation

The calculated energy bandgap (E_g) of the [BTB]^{TF} and [ZrO$_2$+BTB]^C were computed with the help of absorption spectra. The Tauc's relation is employed to compute the E_g values from absorption spectra:

$$(\alpha h\nu)^m = A(h\nu - E_g) \qquad (1)$$

Where A is independent energy constant and hν is the energy of incident photons and m = 1/2 and 2 for direct (E_g^{dir}) and indirectly allowed (E_g^{ind}) transitions. The E_g^{dir} and E_g^{ind} transitions for the [BTB]^{TF} and [ZrO$_2$+BTB]^C nanocomposite thin films were computed by utilizing Eq. (1). Fig. 8(a-b) shows the plot of $(\alpha h\nu)^{0.5} \times 10^3$ (eV/m)$^{0.5}$ versus photon energy $h\nu$ (eV), for both [BTB]^{TF} and a mixture of [ZrO$_2$+BTB]^C [BTB] thin films (Thickness 150 ± 5 nm) [69]. At higher photon energies, the relationship between (αhν)^2 or (αhν)$^{0.5}$ and (*hν*) are depicted in Fig. 8(a and b)), which denotes that direct and indirect optical transitions are likely for both [BTB]^{TF} and [ZrO$_2$+BTB]^C films. The straight-line portions of these curves are extrapolated to zero to compute the actual value of optical band gaps, E_g^{ind} and E_g^{ind} are (2.251 and 2.252 eV) and (2.596 and 2.649 eV) for both [BTB]^{TF} and [ZrO$_2$+BTB]^C film, respectively.

The values of E_g^{ind} of the [BTB]^{TF} is 2.251 eV, nearly the same for [ZrO$_2$+BTB]^C with 2.252 eV as depicted in Fig. 8(a). Fabrication of [ZrO$_2$+BTB]^C nanocomposite thin films may introduce energy levels inside the bandgap. The same behavior is also observed for E_g^{dir}, which increased from 2.596 ([BTB]^{TF}) to 2.649 eV after fabricating [ZrO$_2$+BTB]^C nanocomposite film.
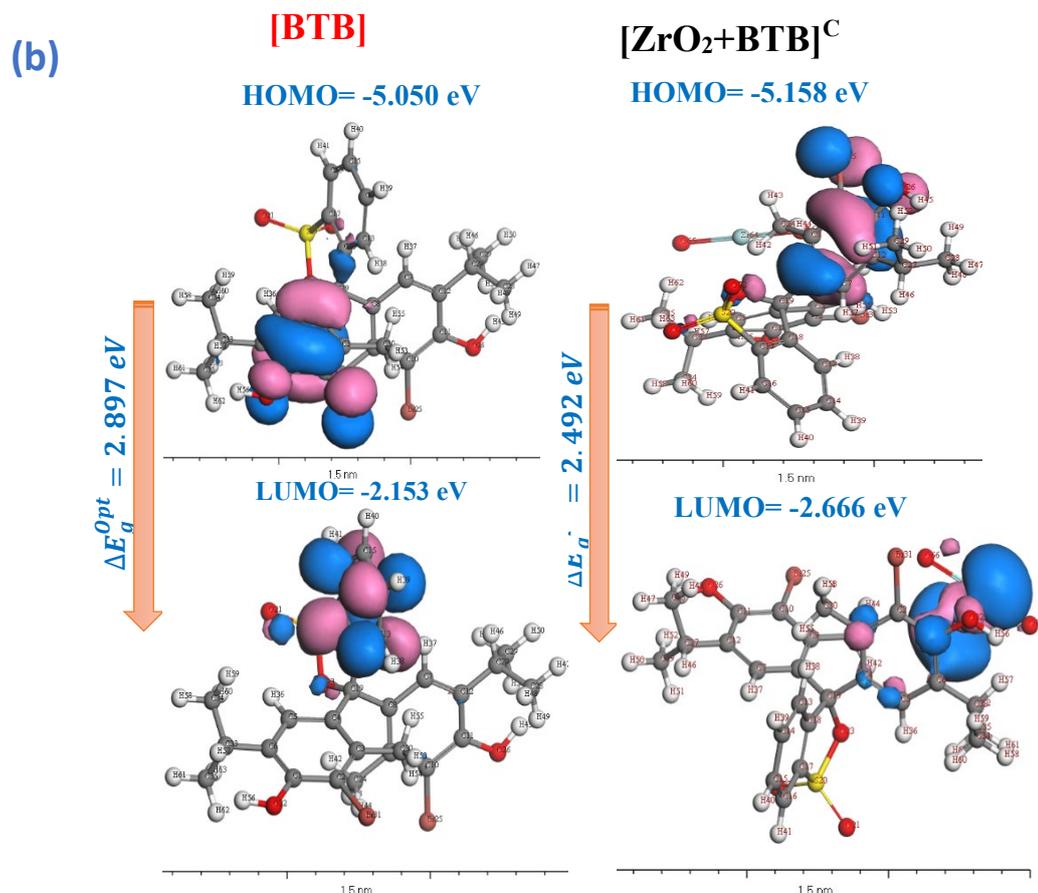

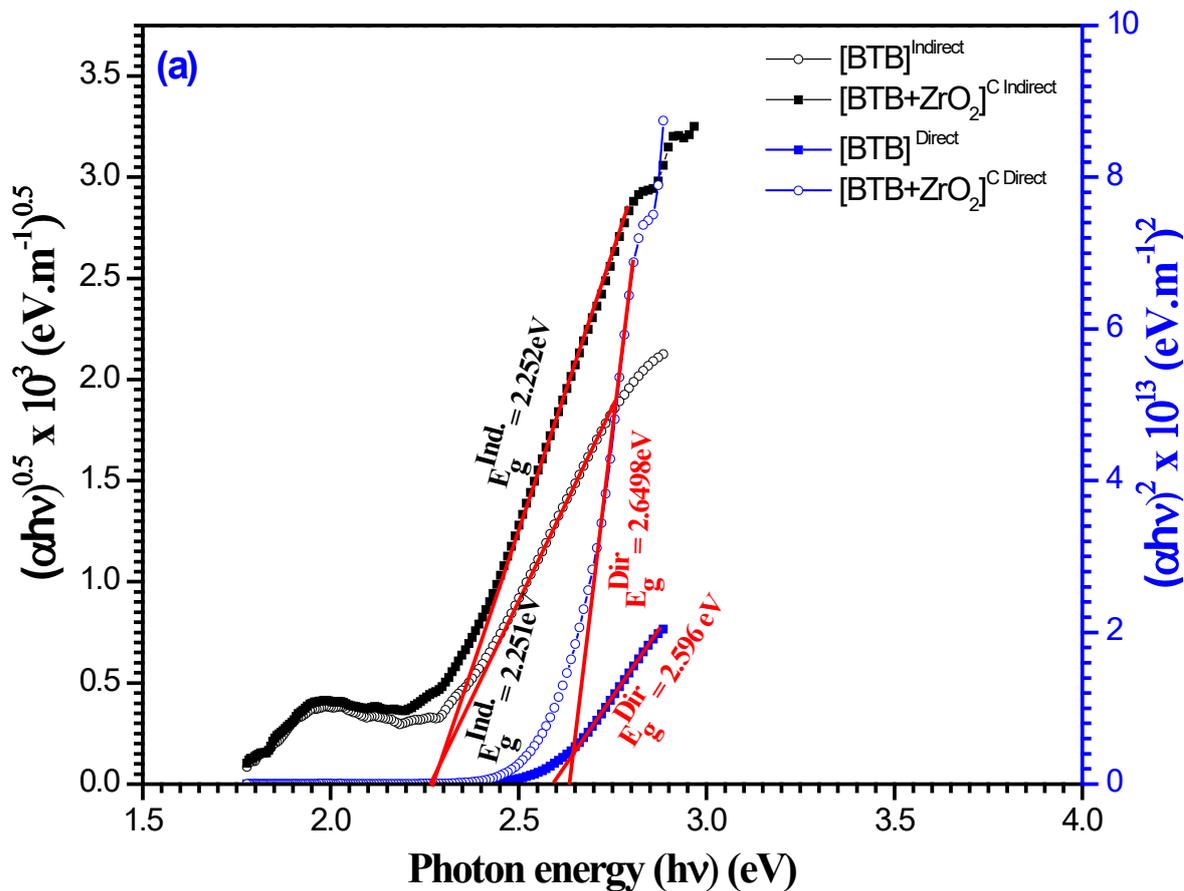

Fig.8 a) The computed band gaps of [BTB]^{TF} and [ZrO$_2$+BTB]^C using Tauc's equation. **b)** Figure is computed HOMO and LUMO using DFT by DMol^3.

Fig. 8(b) shows the DFT/CASTEP program geometry optimization technique used density functional theory (DFT) to estimate direct gap widths of for both $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$. The values of $\Delta E_g^{opt.} = 2.897$ eV and 2.492 eV for $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$, respectively. Since, $\Delta E_g^{opt.}$ is defined as the lower energy value and is assigned to Frankel-exciton generation or a bound electron-hole pair [70-71] is calculated from the difference between HOMO and LUMO by using the DMol^3 method in DFT as shown in Fig. 8(b). The energy gap between the HOMO and LUMO is a critical parameter determining the electronic, optical, redox, and transport (electrical) properties of the $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$ thin films. In comparison with experimental values, the simulated values are very near to the DFT/CASTEP geometry optimization method values acquired by using DFT. Comparing experimental with simulated CASTEP data for the energy gap $\Delta E_g^{opt.}$ found that the variation value between the experimental and simulated values of both $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$. Therefore, simulated CASTEP data and Tauc's model can be utilized effectively to determine $\Delta E_g^{opt.}$ and the electronic transition type, respectively. The difference between the experimental and simulated CASTEP data of the optical energy gap of both $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$ thin films are $\Delta E_g^{opt.} = 0.646\ eV\ (Indirect)$ and $\Delta E_g^{opt.} = 0.301\ eV\ (Direct)$ for $[BTB]^{TF}$. And also, the $\Delta E_g^{opt.}$ values are $0.645\ eV\ (Indirect)$ and $0.157\ eV\ (Direct)$ for $[ZrO_2+BTB]^C$ thin films.

3.7 Optical Dispersion constants

Polymers, dyes, and organic/inorganic compounds are of great importance in the creation of nanomaterials and other equipment such as optoelectronic devices or solar cells. The refractive index n(λ) and extinction coefficient k(λ) values, which included both refraction and absorption based on the interaction between the material being studied and the light-incident. n(λ) has a phase velocity correlation with the dispersion, while k(λ) is linked to a mass reduction coefficient and permits the computation of the electromagnetic wave dissipation rate material. The spectroscopic reflectometry measurement of transmission and reflectance permits the n(λ) and k(λ) versus photon energy (hν) has been studied.
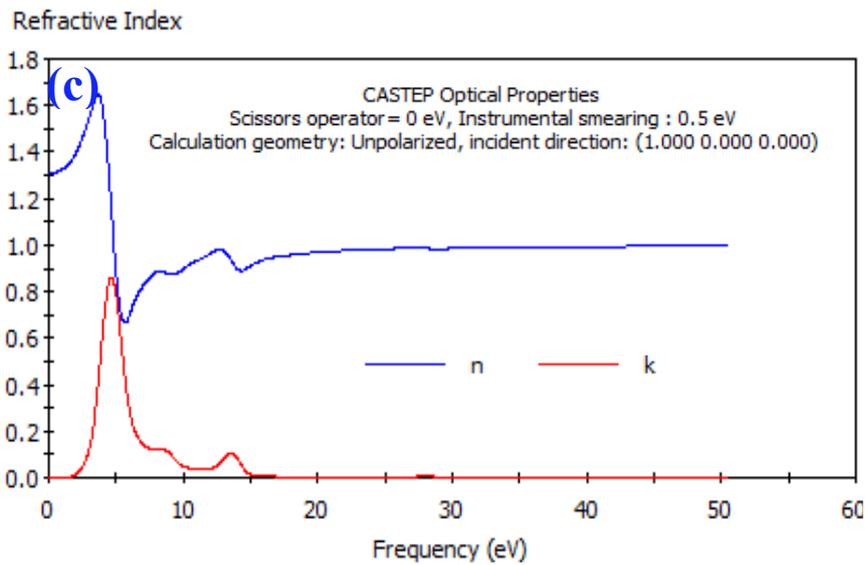

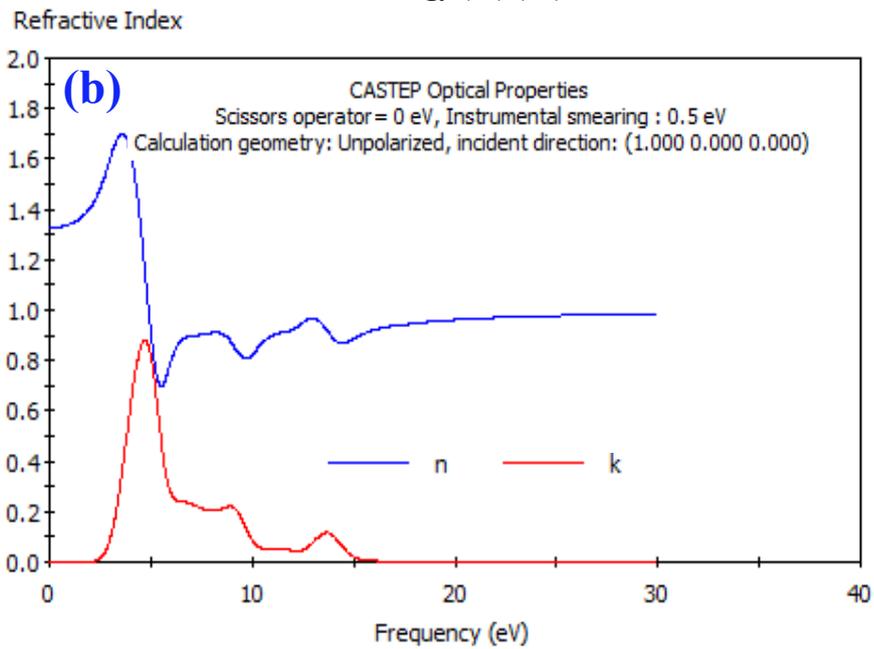

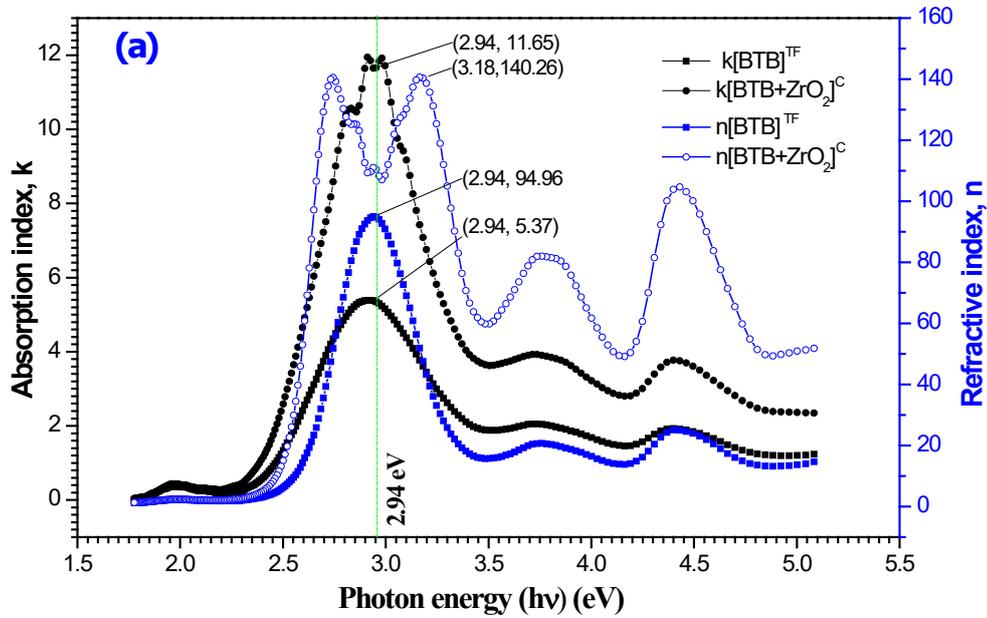

Fig.9 a) The spectral dependence of both the absorption index $k(\lambda)$ and the refractive index $n(\lambda)$ as a function of $h\nu(eV)$ for [BTB]^{TF} and [ZrO$_2$+BTB]^C. **b-c)** Simulated [BTB] and [ZrO₂+BTB]^C using CATSTEP optical properties, respectively.

16

The spectral properties of n(λ) and k(λ) versus (hv) values for [BTB]^{TF}, [ZrO$_2$+BTB]^C as-deposited thin films (thickness 150 nm) over a range 1.0–5.5 eV of (hv) are given in Fig. 9(a-b). Where the mathematical formula of both n(λ) and k(λ) is given by Eqs. (2) and (3) [72] as follows:

$$n(\lambda) = \left(\frac{1+R}{1-R}\right) + \sqrt{\left[\frac{4R}{(1-R)^2}\right] - k^2} \tag{2}$$

$$k(\lambda) = \frac{\alpha\lambda}{4\pi} \qquad \text{and} \qquad \alpha = \frac{1}{d}\ln\left[\frac{(1-R)^2}{2T} + \sqrt{\frac{(1-R)^4}{4T^2} + R^2}\right] \tag{3}$$

As observed from Fig. 9(a), both n(λ) and k(λ) show similar spectral behavior to each other in the photon energy range from $1.0\ eV \leq hv \leq 5.5\ eV$. Since both n($\lambda$) and k($\lambda$) spectral behaviors depend on the type of material. We can classify the patterns into two parts: (i) the first part in $2.25\ eV \leq hv \leq 3.45\ eV$ represents the main characteristic broad peak. For [BTB]^{TF} as-deposited film n(λ) pattern shows a maximum peak of $n_{max.}$ (=9.490) at $hv = 2.94\ eV$, while n(λ) for [ZrO$_2$+BTB]^C film the spectral behavior has been splitting into two peaks with {(i.e, $n_{max.}$ (=14.026) at $hv = 2.55\ eV$) and $n_{max.}$ (=14.026) at $hv = 3.18\ eV$) for the first and second peaks respectively}. Regarding k(λ) parameter in the range, $2.25\ eV \leq hv \leq 3.45\ eV$ is characterized by a sharp peak with ($k_{max.} = 1.165$ at $hv = 2.94\ eV$). (ii) second part in the photon energy $hv > 3.45\ eV$ is characterized by another two broad peaks for both [BTB]^{TF} and [ZrO$_2$+BTB]^C as-deposited thin films. Where, $n_{max.}$ (1st peak) are 1.81 and 8.0 at $hv = 3.72\ eV$ for [BTB]^{TF} and [ZrO$_2$+BTB]^C respectively. While, $n_{max.}$ (2nd peak) are 2.01 and 12.0 at ($hv = 4.41\ eV$) for [BTB]^{TF} and [ZrO$_2$+BTB]^C respectively. On the other hand, $k_{max.}$ (1st and 2nd peaks) are 0.20 ($hv = 3.72\ eV$) and 0.41 ($hv = 4.41\ eV$) for [BTB]^{TF} and [ZrO$_2$+BTB]^C respectively. These obtained maximum peaks were attributed to the $\pi \rightarrow \pi*$ transition due to the presence of benzenoid rings [73-74]. CASTEP method in DFT calculations of [BTB]^{TF} and [ZrO$_2$+BTB]^C as– single crystal was utilized to predict n(λ) and k(λ) values (Fig. 9-b). It is also important to note that the simulation curve presents an approximate similarity for n(λ) and k(λ) with a shift towards the highest energies with lower peak intensities. The maximum peaks obtained for n(λ) and k(λ) are obtained $hv \cong 4.15 - 4.50\ eV$.

3.8 Dielectric constants and optical conductivity

Complex dielectric function (ε^*) is related to both n(λ) and k(λ) as [75,76]:

$$n(\lambda) + ik(\lambda) = \sqrt{\varepsilon^*} \tag{4}$$

Where the real and imaginary parts of ε^* are $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$, respectively. The real dielectric constant ($\varepsilon_1(\lambda)$) generally relates to dispersion, while the imaginary dielectric constant ($\varepsilon_2(\lambda)$) provides a measure to the dissipative rate of the wave in the medium [77]. Also, it indicates the loss of energy in

a dielectric material through conduction slow polarization currents and other dissipative phenomena. Where the loss factor expressed by the ratio $\varepsilon_2(\lambda)/\varepsilon_1(\lambda)$. Both $\varepsilon_1(\lambda)$, and $\varepsilon_2(\lambda)$ are evaluated using the relation [78]:

$$\varepsilon_1(\lambda) = n^2 - k^2 \quad and \quad \varepsilon_2(\lambda) = 2nk \tag{5}$$

Fig. 10(a-c) show the spectra of $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ as a function of photon energy experimentally and simulated by using the CASTEP method in DFT for as-deposited $[BTB]^{TF}$ and $[ZrO_2+BTB]^{C}$ thin films. From Fig.10, it is observed, the calculated values of the real part $\varepsilon_1(\lambda)$ are higher than of the imaginary part $\varepsilon_2(\lambda)$ for both $[BTB]^{TF}$ and $[ZrO_2+BTB]^{C}$ thin films. Also, $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ parts for $[BTB]^{TF}$ films spectral profile have the same trend of behavior. During the whole spectra ranged from $1.5\ eV \leq h\nu \leq 5.5\ eV$, $[BTB]^{TF}$ pattern is characterized by a main broad peak in the photon energy range $2.5\ eV \leq h\nu \leq 3.5\ eV$. Since the maximum value of both $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ has been obtained correspond to $h\nu = 2.94\ eV$. But, in the case of $[ZrO_2+BTB]^{C}$ nanocomposite thin film, the spectral behavior is characterized by three broad peaks corresponding to photon energies of 2.94 eV, 3.75 eV, and 4.41 eV. At the same time, $\varepsilon_1(\lambda)$ maximum spectral peak of $[ZrO_2+BTB]^{C}$ nanocomposite film has severed into two peaks corresponding to 2.71 eV and 3.17 eV respectively. The creation of the three peaks in a photon energy range 1.5eV to 5.5 eV in $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ patterns could be attributed due to $\pi \rightarrow \pi^*$ electronic transition. Also, the
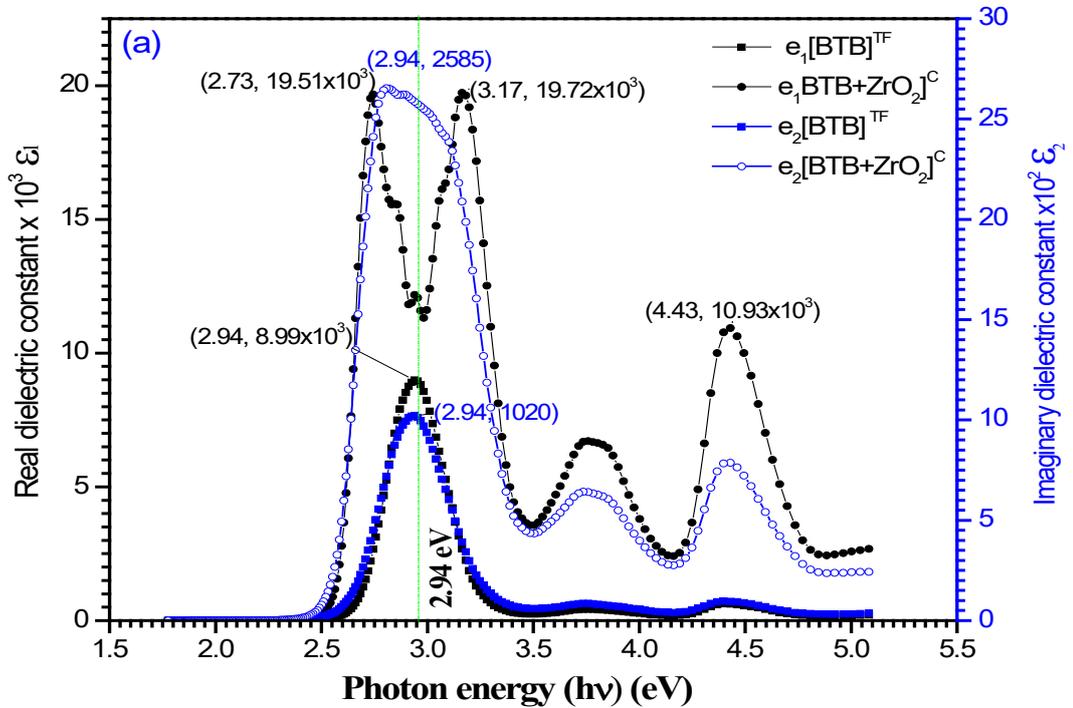

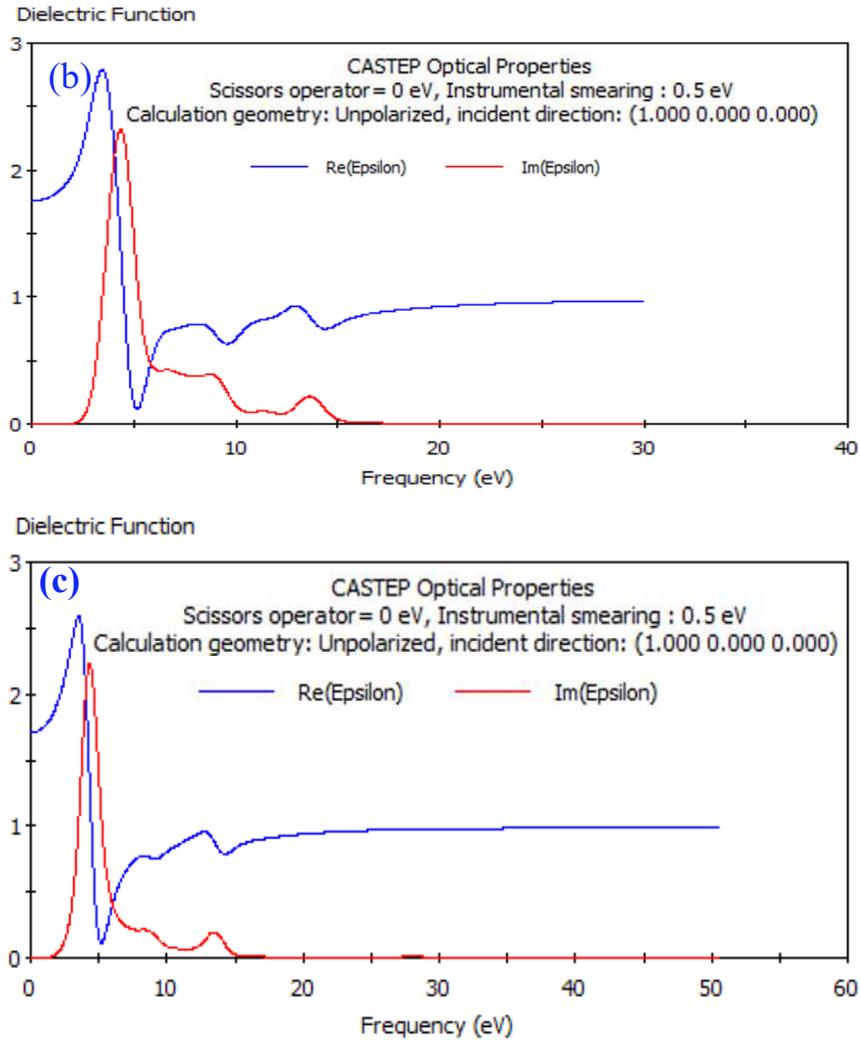

Fig. 10 a) Experimental $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ via hv for [BTB]TF and [ZrO$_2$+BTB]^C, b) ε_1 and ε_2 simulation optical prop erties for [BTB] and [ZrO$_2$+BTB]^C by using CASTEP method in DFT

Interactions between photons and electrons in both [BTB]^{TF} and [ZrO2+BTB]^C leads to the variations of both $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ profiles. Additionally, the ratio $\frac{\varepsilon_1(\lambda)}{\varepsilon_2(\lambda)}$ are 10 times, for both [BTB]^{TF} and [ZrO2+BTB]^C films, which means that $\varepsilon_1(\lambda)$ is predominated. By using the CASTEP method in DFT, the maximum values of $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ are related to frequency $\cong 3.12eV$ and 4.89 eV for [BTB}^{TF}, respectively, as shown in Fig. 10b. And, the maximum values of $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ are related to frequency $\cong 3.75eV$ and 5.00eV for [ZrO2+BTB}^{C}, respectively, as shown in Fig. 10c.

Finally, it is remarked that, the outcomes from the experimental technique and CASTEP calculations for the maximum peaks of $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ for [BTB]^{TF} and [ZrO$_2$+BTB}^{C} films is located at range hv $\cong 2.71$-3.17 eV(precisely at $hv= 2.94$ eV) . Since, $\varepsilon_1(\lambda)$ is predominated case, the actual comparison must be between the $\varepsilon_1(\lambda)$ values in experimental method and $\varepsilon_1(\lambda)$ calculated from the CASTEP method which overall is in the range of $hv \cong 3.75$-4.5 eV. The electrical conductivity of any semiconducting materials depends initially on the state of the delocalization of the electrons. The movement of charge carriers such as ions and electrons in the crystal lattice, and induced by the incident

electromagnetic waves, stimulate also an increase of conductivity. While the optical response of the material is determined by the complex optical conductivity $\sigma^*(\lambda)$ established by the following expression [79]:

$$\sigma^*(\omega) = \sigma_1(\omega) + i\sigma_2(\omega) \tag{6}$$

Where $(\sigma_1(\lambda))$ is the real part and $(\sigma_2(\lambda))$ is the imaginary part of the optical conductivity. The values of real and imaginary parts are given by the relations [80,81]:

$$\sigma_1(\omega) = \omega\varepsilon_2\varepsilon_0 = 2\omega\varepsilon_0 nk \tag{7}$$

$$\sigma_2(\omega) = \omega\varepsilon_1\varepsilon_0 = \omega\varepsilon_0(n^2 - k^2) \tag{8}$$

Where ω is the angular frequency, ε_0 *the* permittivity of free space (free space dielectric constant). The dependence of the real and imaginary parts of the optical conductivity on the incident photon energy of our samples is shown in Fig.11 (a-c).

Fig. 11 shows the dependence of optical conductivity of $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$ thin films (150nm thickness) with photon energy ranged from $1.5\,eV \leq hv \leq 5.5\,eV$. Where, Fig. 11a displays the experimental behavior of the optical conductivity with hv, while Figs.11 (b and c) demonstrates the simulation using CASTEP in the DFT method of $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$, respectively. From Fig. 11a, it is observed that, the spectral behavior of σ_1 and σ_2 have the same pattern as that $\varepsilon_2(\lambda)$ and $\varepsilon_1(\lambda)$, respectively. Since Optical conductivity activity may be attributed due to the excitation of electrons.

The real conductivity (σ_1) for $[BTB]^{TF}$ has a unique characterized broad peak of $(4\times10^6\,\Omega^{-1}\,m^{-1}$ at hv= 2.94 eV), while $[ZrO_2+BTB]^C$ thin film has three distinct peaks at $(72.75\times10^5, 8.39\times10^6,$ and $65.14\times10^5\,\Omega^{-1}\,m^{-1})$ corresponding to photon energies (2.94, 3.75, and 4.41eV), respectively. On the other hand, σ_2 imaginary optical conductivity, for $[BTB]^{TF}$ still has a single peak at the same photon energy as σ_1. But, in the case of $[ZrO_2+BTB]^C$ a splitting in the 1st distinguished peak into two of energies 2.71 and 3.18 eV, respectively. Also, an increase in the maximum values of σ_2 of both 2nd and 3rd peaks. Enhances of the optical conductivity of $[ZrO_2+BTB]^C$ film may be attributed to the high absorption coefficient associated with charge ordering effect and refractive index. Where the optical conductivity and the absorption coefficient are related by the following relation [82-83]: $\sigma = \alpha nc/4\pi$, where c is the light speed, and α is the absorption coefficient. This relation tells us that the optical conductivity is linearly dependent on the refractive index and absorption coefficient.

Finally, Fig. 11 (b-c) show the spectral dependence of optical conductivity σ(ω) versus photon energy (hv) for $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$ as-single by using CASTEP in the DFT simulation method. The simulation and experimental behavior of optical conductivity σ (ω) are similar in behavior with different intensity of peaks and the photon energies (hv) values. The simulation curves for $[BTB]^{TF}$ and

$[ZrO_2+BTB]^C$ compounds indicate strong conformity compared with the experimental curve. Both σ_1 and σ_2 of $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$ have a directly proportional with increasing $h\nu$ up to 4.50 eV.
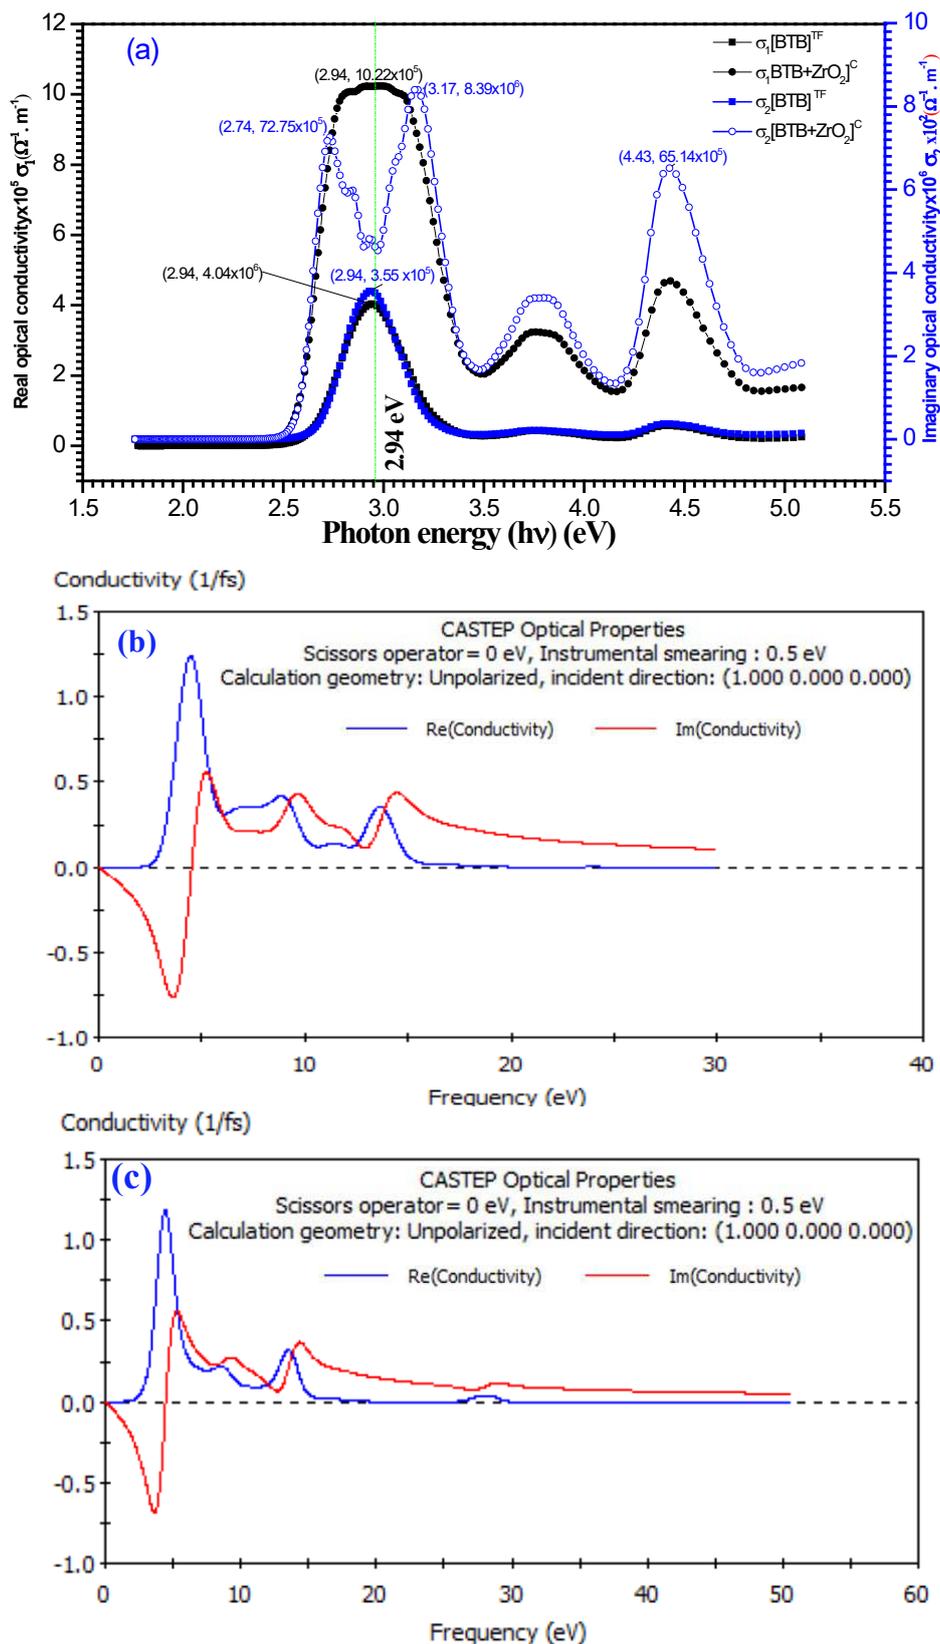

Fig. 11 a) Experimental σ_1 and σ_2 via $h\nu$ for $[BTB]^{TF}$ and $[ZrO_2+BTB]^C$, b-c) σ_1 and σ_2 simulation optical properties for $[BTB]$ and $[ZrO_2+BTB]^C$ by using CASTEP method in DFT, respectively.

Conclusion

In this work, novel bromothymol blue dyes [BTB]^{TF} and [ZrO$_2$+BTB]^C as-deposited thin films are fabricated by using the Sol-gel spin coating technique. The molecular structural characteristics of [BTB]^{TF} and [ZrO$_2$+BTB]^C compounds are determined using FTIR, MEP, ED techniques. The crystalline structure and morphology of [BTB]^{TF} and [ZrO$_2$+BTB]^C films are investigated by XRD and SEM techniques. Since the nanofibers of [ZrO$_2$+BTB], ^{C} film is attributed to the presence of [ZrO$_2$]^{NPs}. the XRD reveals that the same crystal structure was remarked for [BTB]^{TF} and [ZrO$_2$+BTB]^C (Orthorhombic) with space group (P6$_1$). Optical dispersion parameters, dielectric and optical conductivity properties of [4-[BTB]^{TF} and [ZrO$_2$+BTB]^C as-deposited thin films are calculated experimentally and by simulation by using CASTEP in the DFT method. There is a good agreement between optical energy gap values determined by Tauc's equation calculations and that obtained by DFT (DMol^3) computations. Direct-allowed electronic transition is the predominated case.

Figures
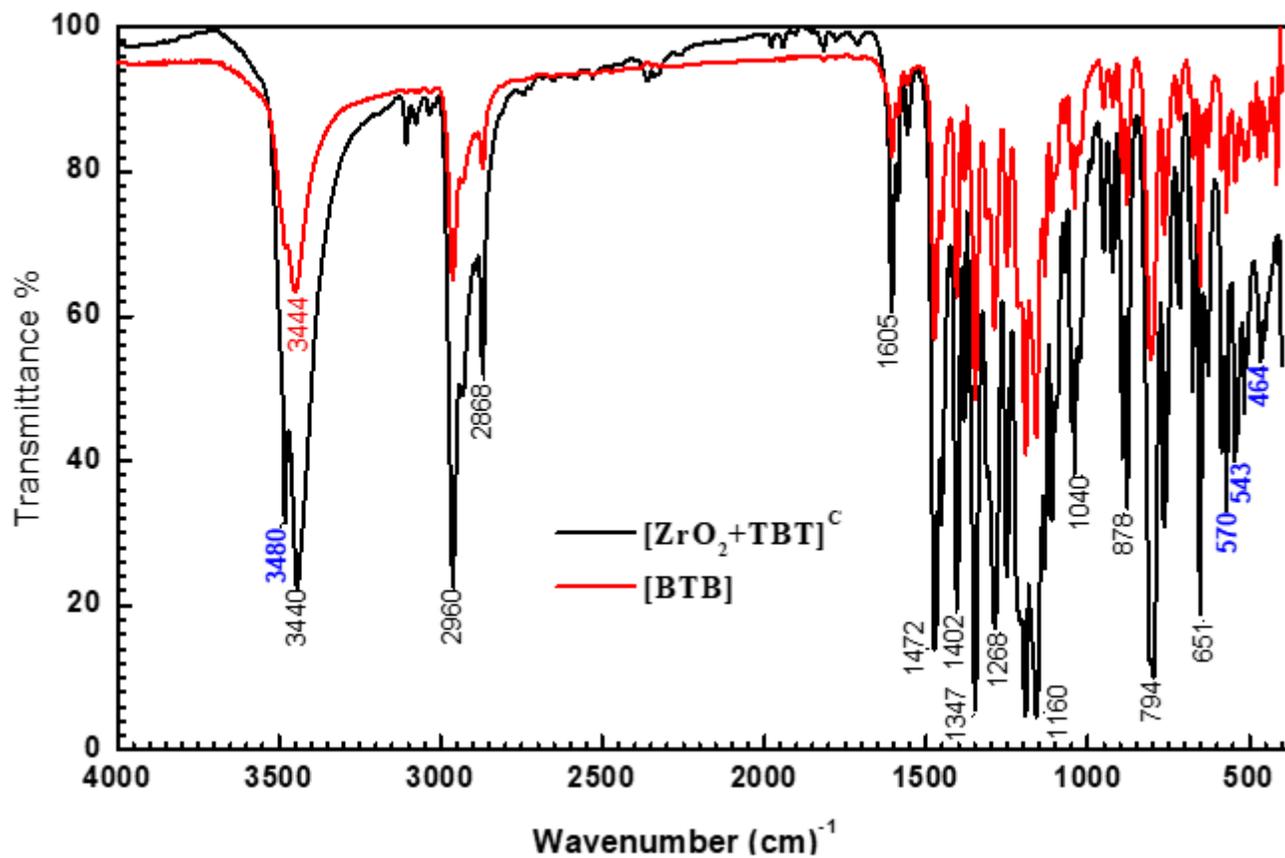

Figure 1

The FTIR spectra experimental data of [BTB] and [ZrO2+BTB]C.
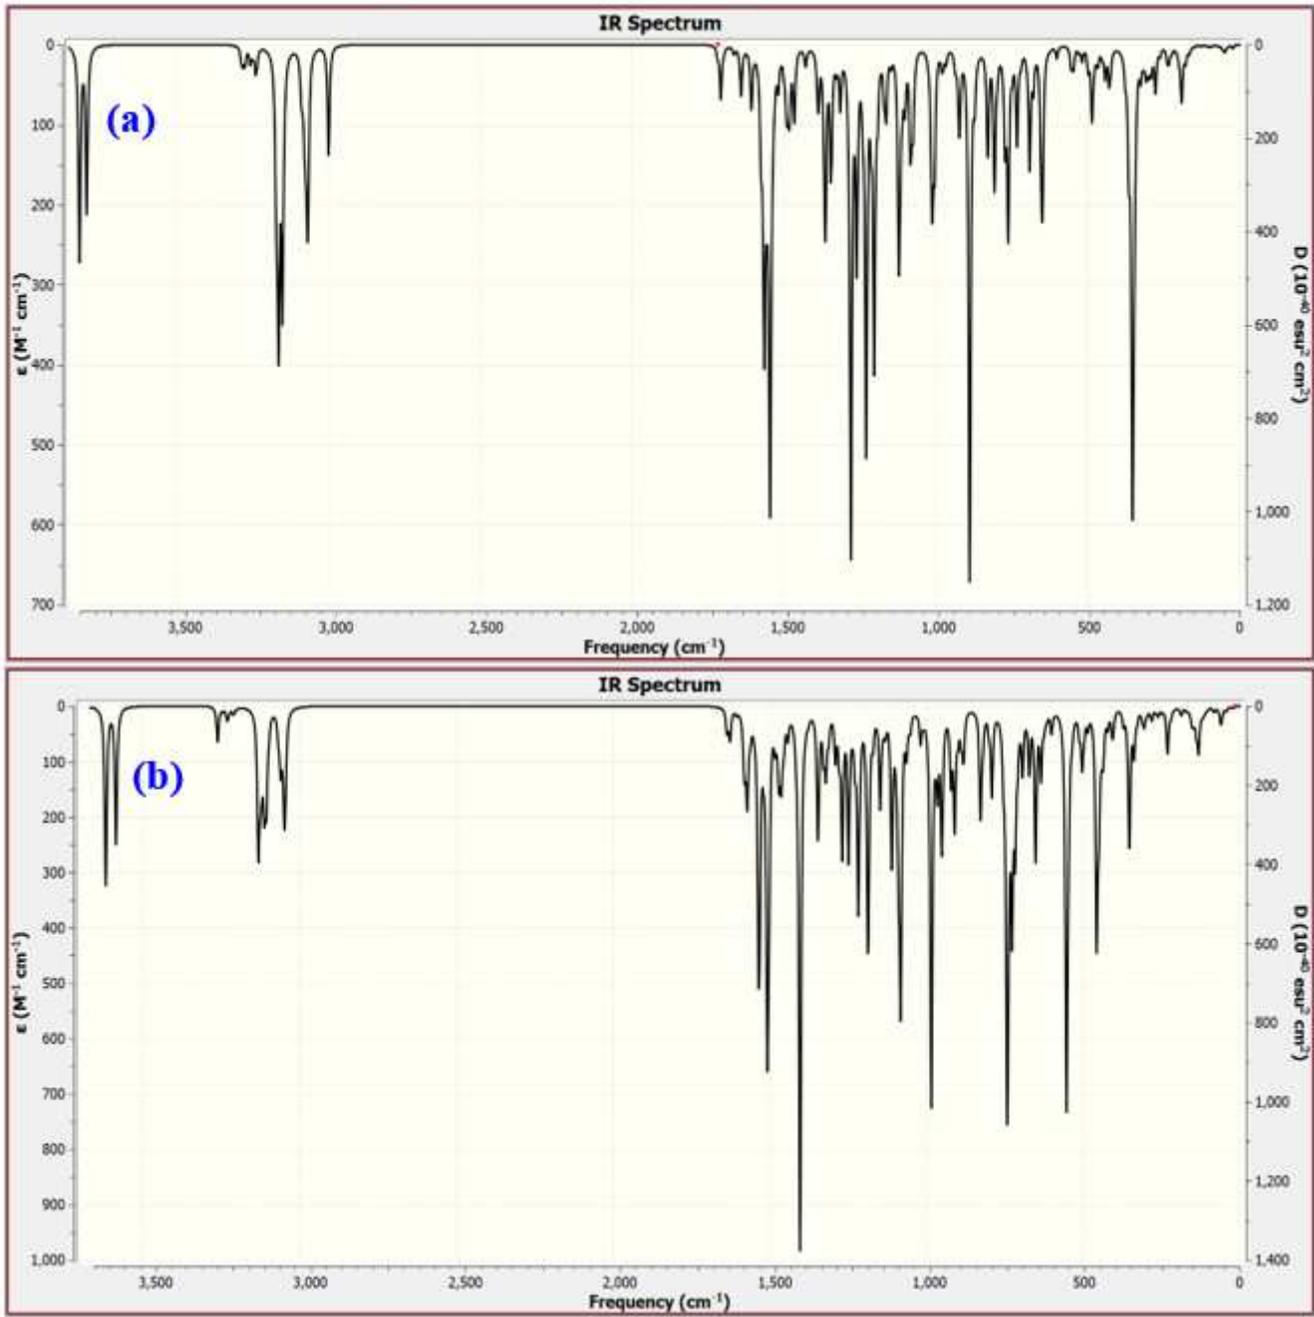

Figure 2

The FTIR spectra Gaussian data of [BTB] and [ZrO2+BTB]C.
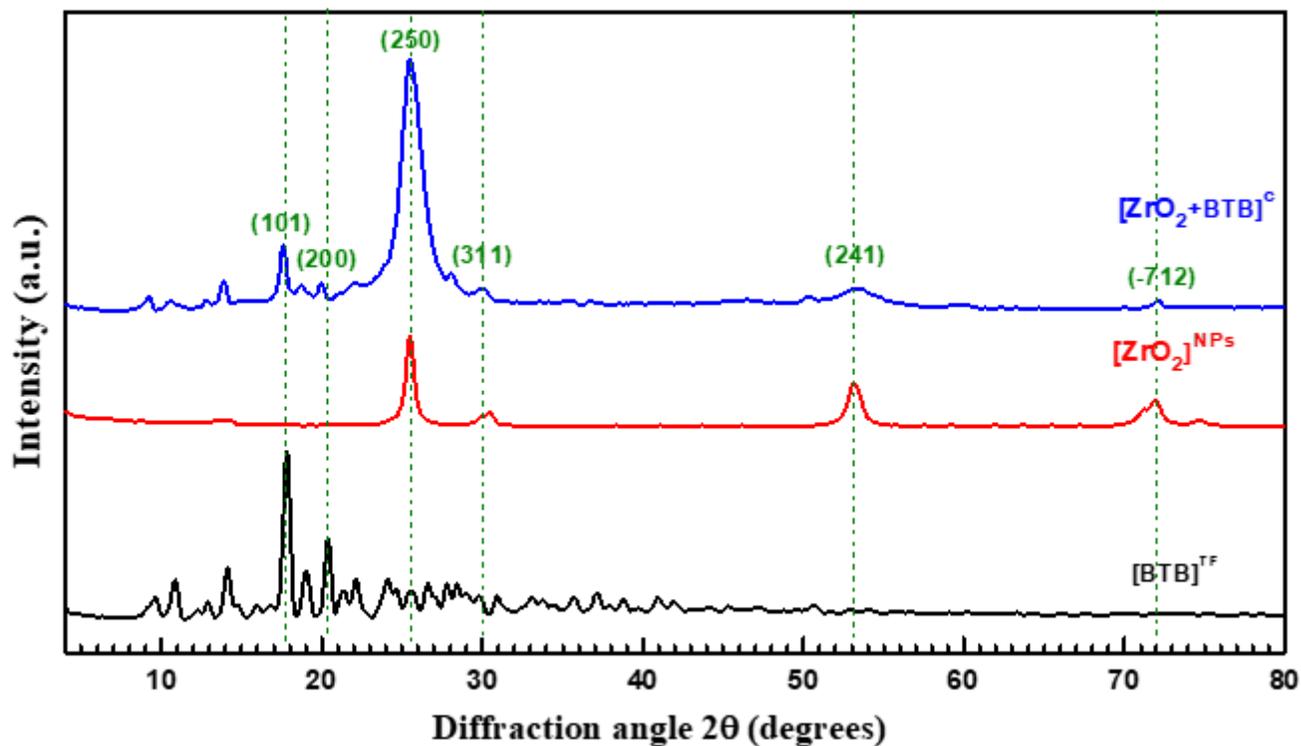

Figure 3

Experimental XRD pattern of [BTB]TF, [ZrO2]NPs and [ZrO2+ BTB]c
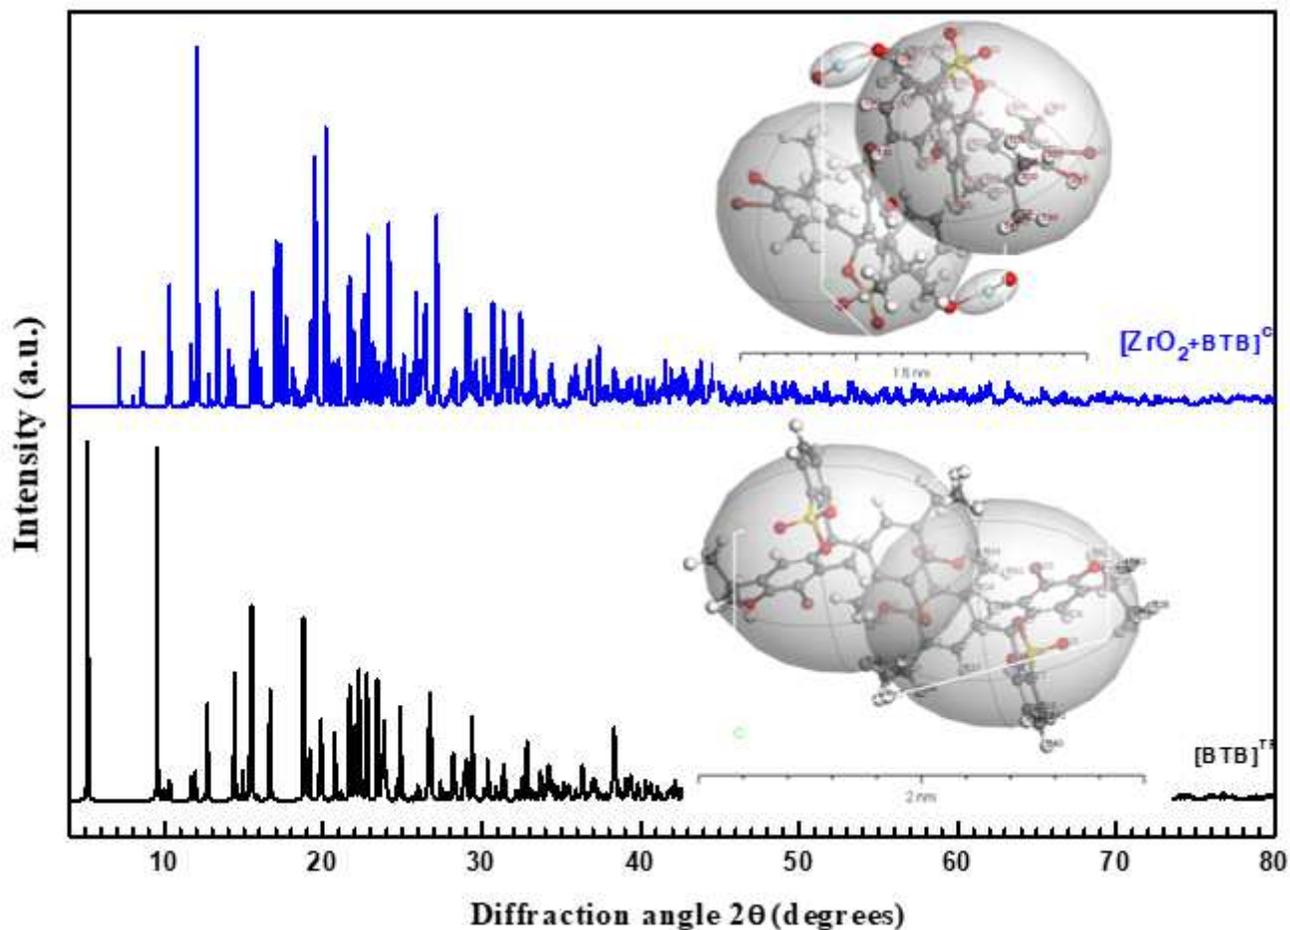

Figure 4

Simulation XRD pattern of [BTB]TF and [ZrO2+ BTB]c by using Material Studio.
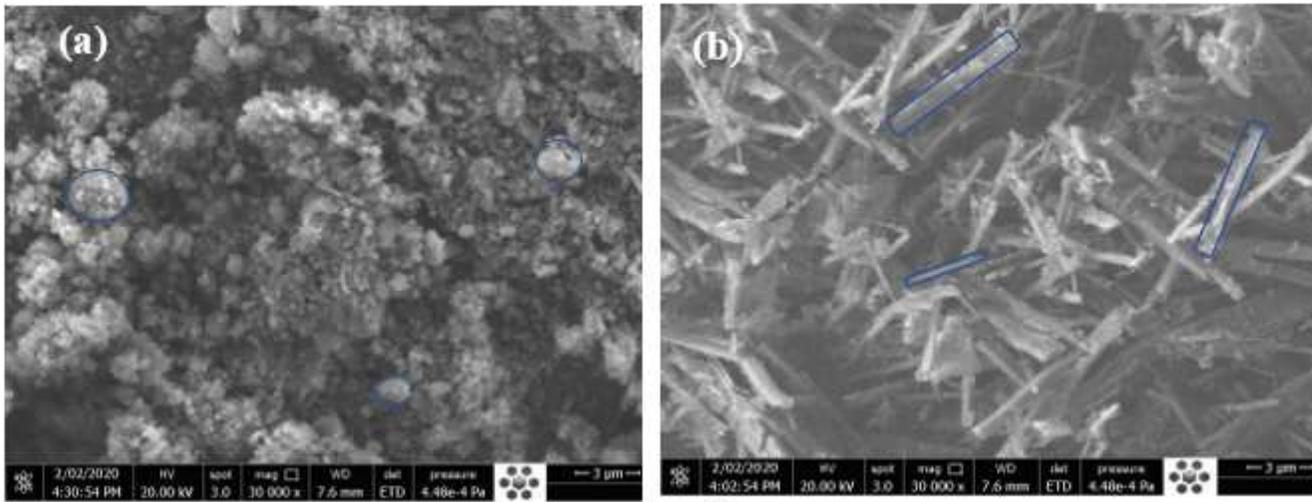

Figure 5

Top view of the prepared [BTB]TF and [ZrO2+ BTB]C thin films (150 nm) using the SEM technique.
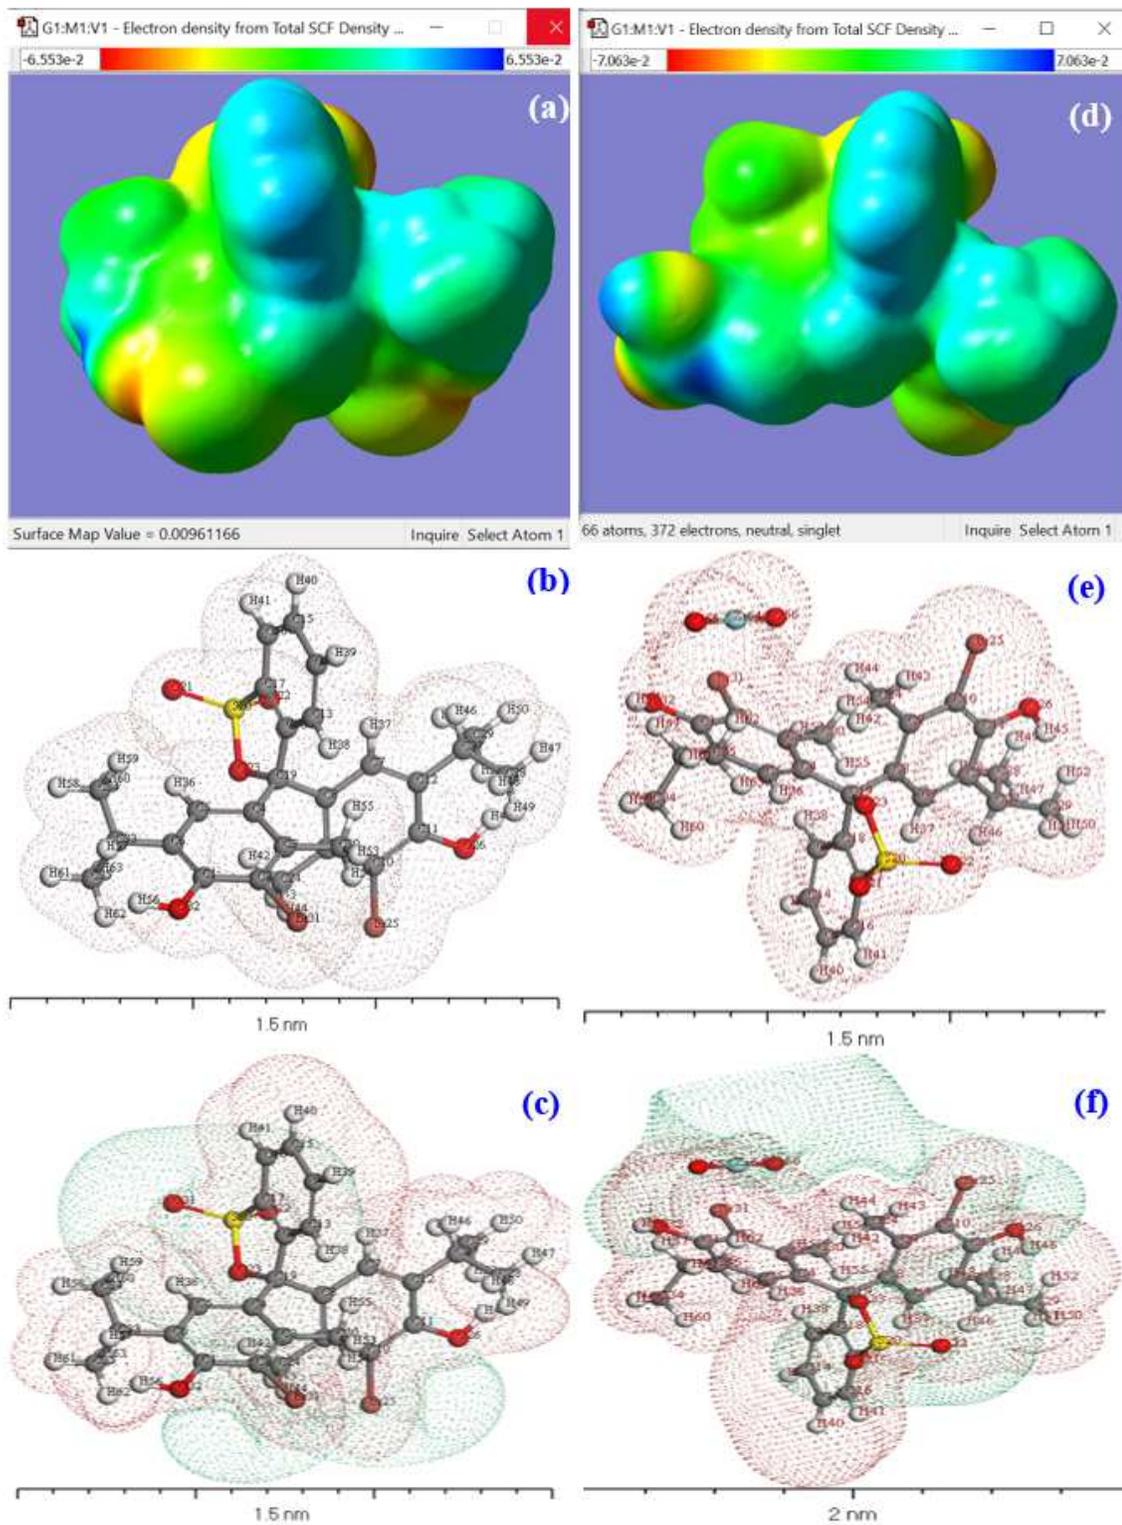

Figure 6

a) MEP of [BTB]; b) Electron density of [BTB] ; c) Potential of [BTB], d) MEP of [ZrO2+BTB]C; e) Electron density of [ZrO2+BTB]C and e) Potential of [ZrO2+BTB]C by using DFT calculation in material studio and Gaussian software programs
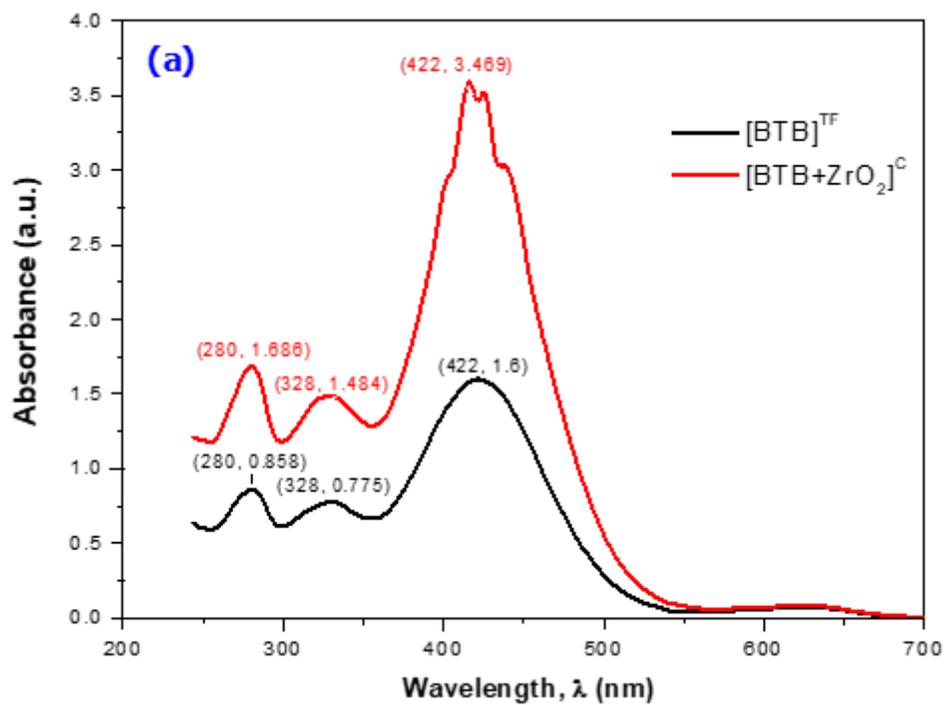

Figure 7

a) UV−vis absorption spectra of [BTB]TF and [ZrO2+BTB]C
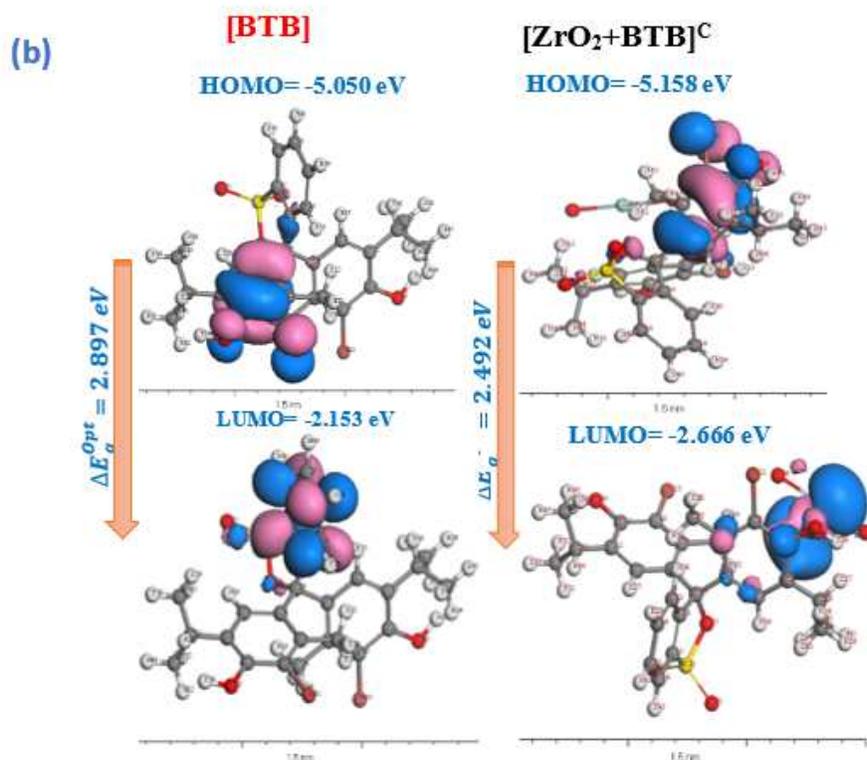

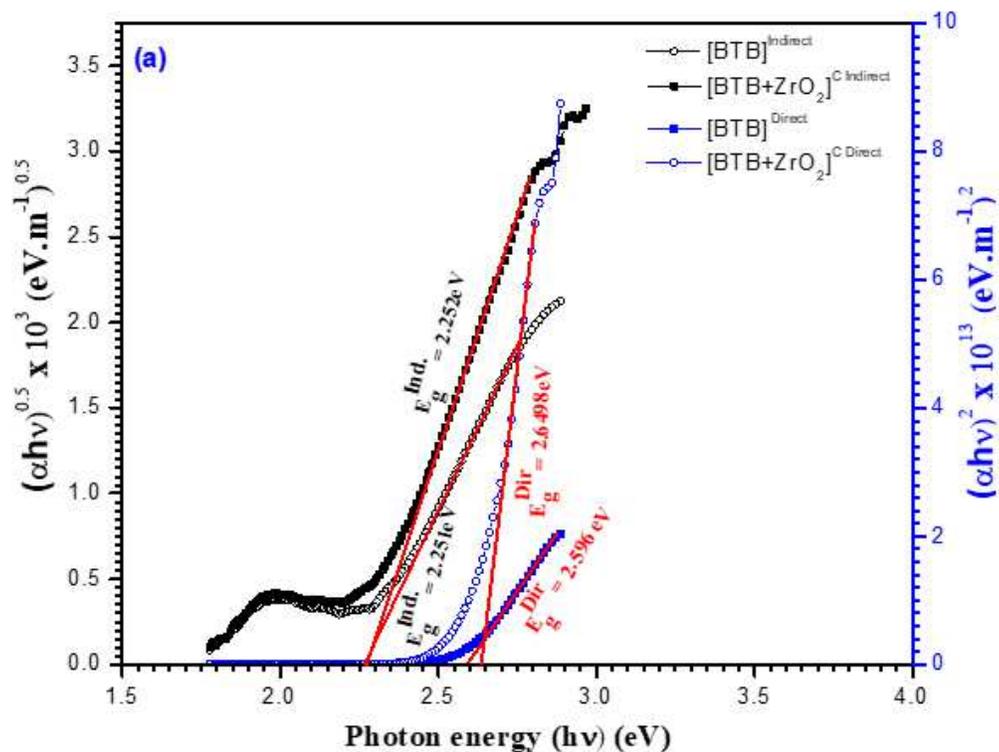

Figure 8

a) The computed band gaps of [BTB]TF and [ZrO2+BTB]C using Tauc's equation. b) Figure is computed HOMO and LUMO using DFT by DMol3.
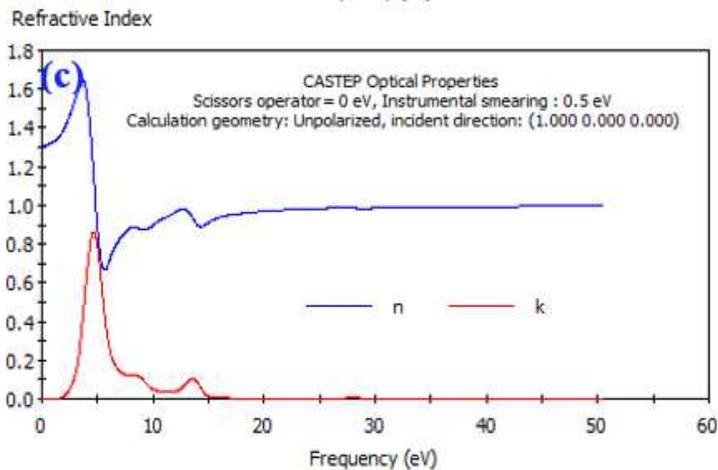

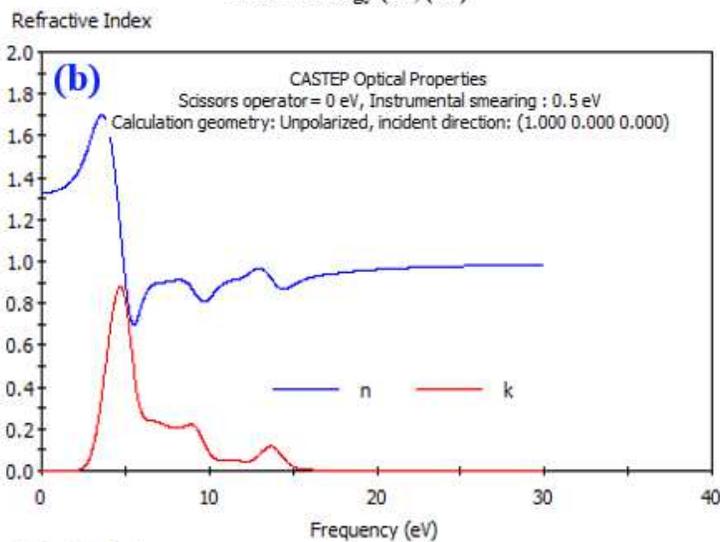

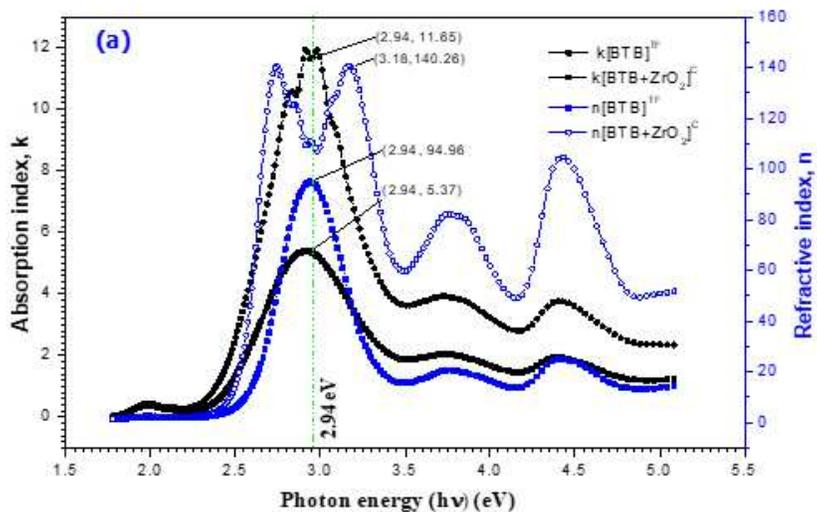

Figure 9

a) The spectral dependence of both the absorption index k(λ) and the refractive index n(λ) as a function of hv(eV) for [BTB]TF and [ZrO2+BTB]C. b-c) Simulated [BTB] and [ZrO2+BTB]C using CATSTEP optical properties, respectively.
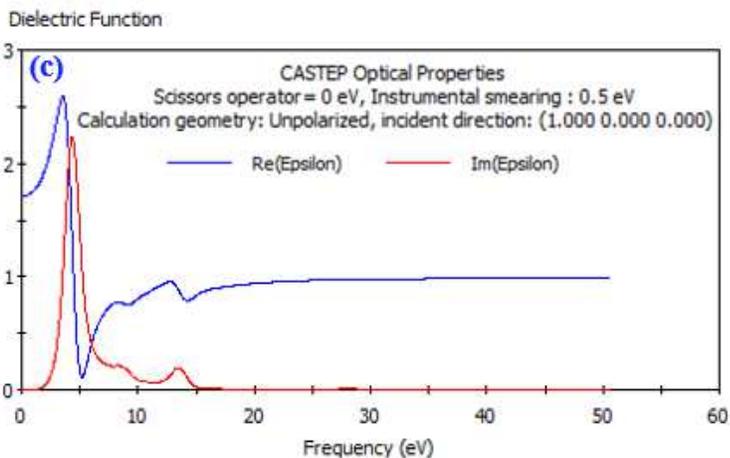

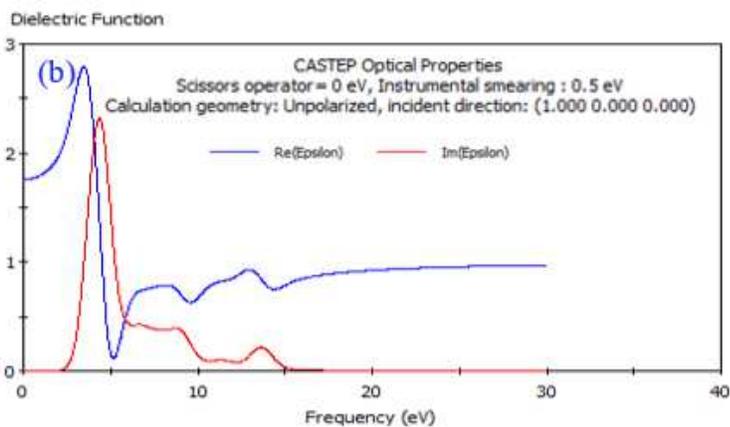

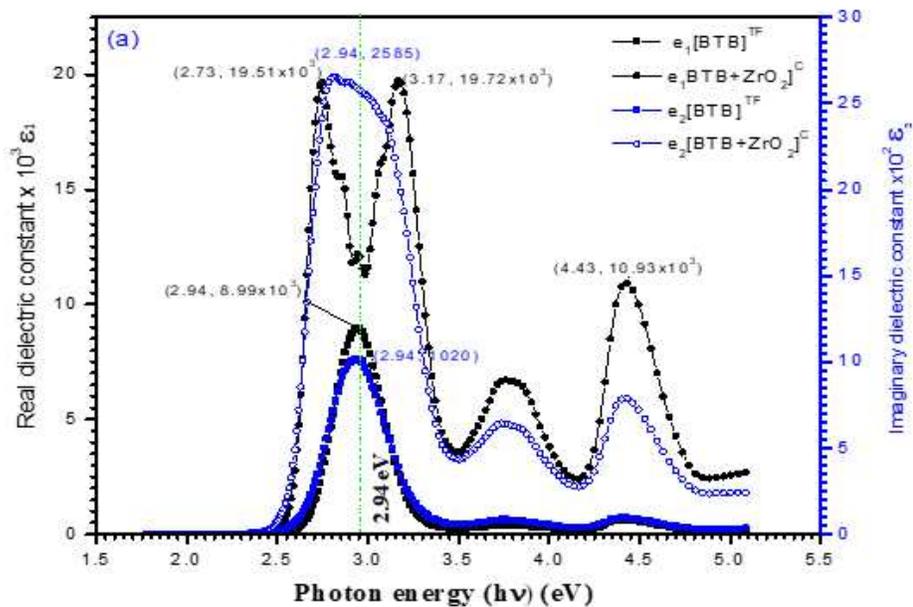

Figure 10

a) Experimental ε_1 (λ) and ε_2 (λ) via hv for [BTB]TF and [ZrO2+BTB]C, b) ◻1 and ◻2 simulation optical prop erties for [BTB] and [ZrO2+BTB]C by using CASTEP method in DFT
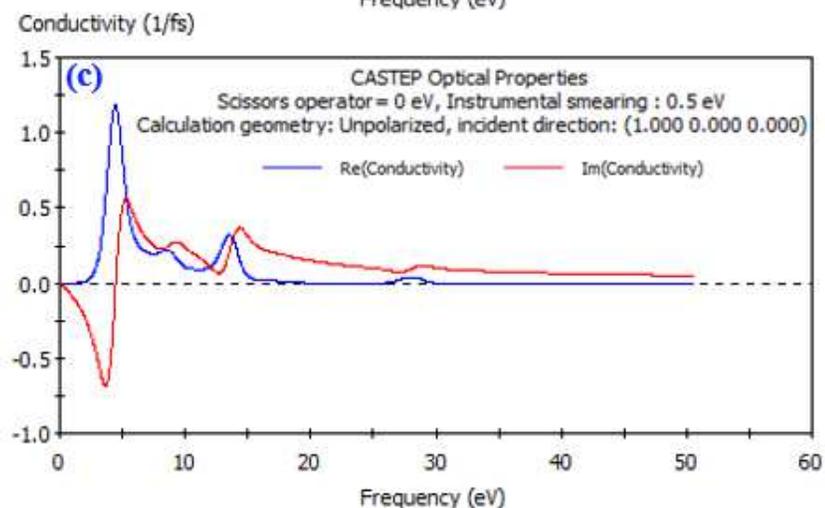

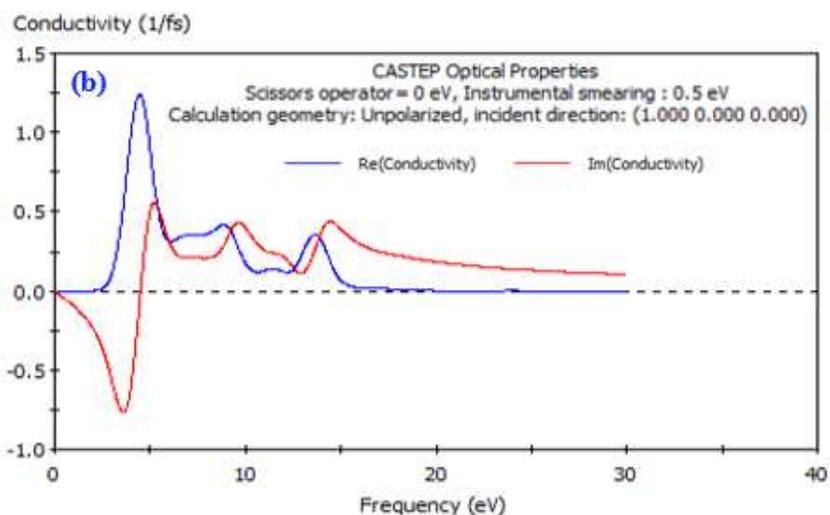

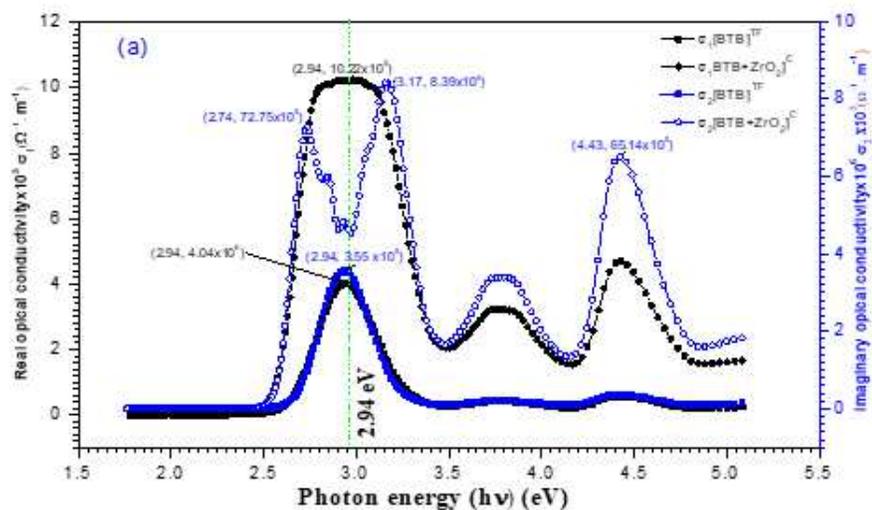

Figure 11

a) Experimental σ1 and σ2 via hv for [BTB]TF and [ZrO2+BTB]C, b-c) σ1 and σ2 simulation optical properties for [BTB] and [ZrO2+BTB]C by using CASTEP method in DFT, respectively.
