Abstract

Background:

Globally, surgical care plays a vital role in healthcare. Unfortunately, complications arise in approximately 5-18% of surgical procedures. However, research has shown that following the surgical safety checklist provided by the World Health Organization (WHO) can significantly reduce these complications and surgery-related fatalities. The objective of this study was to assess the accuracy and completion of the WHO Surgical Safety Checklist.

Method:

From September 3, 2022, to February 28, 2023, a comprehensive observational study was conducted involving 300 patients who underwent elective and emergency surgeries. The completion rates for the different stages of surgery, namely sign-in, time-out, and sign-out, were determined using the SPSS 22.0 software.

Result:

In our research, we specifically examined the completion of the checklist for 300 patients who underwent important procedures within a span of five months. For each patient, we ensured that their identities, procedures, and consent were verified with a 100% success rate. Additionally, we thoroughly checked the anesthesia equipment and drugs for safety in every case. Furthermore, all essential images were consistently displayed for each patient, achieving a 100% adherence to this crucial aspect of the process.

Conclusion:

In general, the level of completeness of the checklist was satisfactory across the sign-in, time-out, and sign-out phases. While this study did not assess the specific outcomes, it is presumed that incomplete data may have exposed patients to potential perioperative complications.

Introduction

Surgical procedures are a vital part of health care around the world, with about 234 million operations performed every year [1,2]. This number is higher than the number of births each year [3]. However, surgery also carries a risk of complications, which happen in 5-18% of cases [4,6]. These complications can lead to serious harm or death for patients, affecting one out of every 310 operations [5,7,8]. Therefore, it is important to prevent medical errors as much as possible [7]. One way to do this is to use the WHO Surgical Safety Checklist, which is a global tool to improve patient safety during surgery [9]. The checklist covers the essential aspects of surgical care, such as infection prevention, anaesthesia safety, teamwork and communication, and quality measurement [10,11]. There is strong evidence that nearly half of the complications or adverse outcomes resulting from surgical operations can be avoided [11,12]. Studies have shown that using the checklist can reduce the rate of major complications from 11% to 7% and reduce the rate of mortality by 53% (from 1.5% to 0.8%) [2,7]. The checklist has four main components that
correspond to different stages of the surgical process [13]. The use of the checklist (following all four components) has increased over time and has been associated with lower rates of postoperative problems and mortality [14,15]. However, the effectiveness of the checklist depends on how well it is implemented in each hospital. Some challenges include integrating it into the workflow and measuring its impact on safety [16]. To ensure successful implementation, hospital leaders and staff need to be actively involved in the process, communicate and collaborate across disciplines, provide training and feedback, and conduct regular audits [2,14,15,17,20]. It has been shown that there is a direct link between better outcomes and the use and adherence to the checklist [21]. Therefore, to achieve the full benefits of the checklist, it is necessary to ensure proper compliance and implementation. The purpose of this study is to evaluate how well the WHO checklist is completed at Ribat University Hospital operating room.

Aims and objectives

Aim

The aim of this study was to assess the completion of all the surgery checks and briefing/debriefing for each operative and surgical procedure at Ribat University Hospital.

Objectives

The main objectives of this study are:

1) To identify the missing steps in completing the surgical safety checklist 2) To ensure that the right patient and the right site are operated on by the OR team 3) To enhance the safety of anesthesia practices 4) To prevent infections at the surgical site and 5) To facilitate good communication among the OR team.

Methods

A prospective observational cohort study was conducted at Ribat University Hospital from September 03, 2022 to February 28, 2023

Audit population

All surgical procedures done at Ribat University Hospital.

Audit sample

All surgical procedures done during the study period.
Data collection method and analysis

The information was collected by direct observation and a checklist-based chart review. The audit proforma was created by converting the standards into question forms with the integrated checking options "Yes" and "No". Google Forms were used to enter the data, which were then exported into SPSS version 22.0 for analysis. Descriptive analysis was performed. Results are expressed in frequencies and percentages using table and figure. The work has been reported in line with the STROCSS criteria [22].

Audit standards

The WHO has created a worldwide surgical safety checklist to reduce the frequency of surgical complications by strengthening the commitment of clinical professionals to address safety issues in surgical settings. The checklist is divided into three sections: before induction of anesthesia, before skin incision, and before any team member exits the operating room. The gold standard was a 100% completion rate of high-quality, safe surgery checks before each operation or surgical procedure (Table 1).

Results

We examined the completion of the checklist for 300 patients who underwent major operations in six months in our study. The identity, procedure and consent of all patients (100%) were verified as the standard requires in its first part (before anaesthesia was administered). The anaesthesia machine and medications were also scrutinized for safety for all patients. The allergic status of the patient was queried and documented in 97.01% of the patients. Essential images were displayed for all patients (100%). (Table 2). The highest completeness of the checklist was seen in February and the lowest completeness of the checklist was seen in September (Figure 1).

Discussion

The WHO checklist has three main parts, which are done at specific times during surgery: The first part (Sign-in) is before giving anesthesia to the patient; the second part (Time-out) is before making the surgical incision; and the third part (Sign-out) is before transferring the patient to the recovery room [Figure. 2].
Important information can be reviewed, shared, and communicated between all team members involved in surgery at each of these times. The checklist is meant to improve surgical outcomes and, as a result, healthcare quality in general. However, its introduction and sustainability are always a big challenge. The Sign-in period was more completed than the Time-out and Sign-out periods in this study. These items are important in avoiding the most common mistakes that seriously harm patients [11]. This finding is almost similar to a study done in India [6]. In addition, confirming patients’ identity, procedure and consent were 100% completed. This finding is nearly the same as a study done at the University of Gondar in Ethiopia, where only 1.9% was missed in their study [5]. In the current study, the anaesthesia machine and medications check were completed in all patients. This finding is almost consistent with a study done at Yekatit 12 referral Hospital, Addis Ababa, Ethiopia [23]. However, even though they are essential steps, items of aspiration risk, anticipation of a difficult airway, and estimated blood loss were not checked in some cases; all of them could cause death [24]. One of the WHO Surgical Safety Checklist’s main goals is to encourage communication among the surgical team [25]. In the Time-out period, surgical teams are supposed to mention their name and role to each other. In this period, some surgical team members did not mention their name and role to the others. However, this finding is higher than a study done in Thailand in which the majority of the surgical team failed to introduce their name and functional role to others [25]. Essential imaging was displayed during surgery in all patients. This finding is almost in line with studies conducted in different institutions [5,6,25,26,27]. In this study finding, the Sign-out period was less performed compared with other sections. However, this finding is higher than most study findings conducted in different study areas [5,10,26,28]. The presence of adequate operating room nurse staff, which reduces the workload of nurses needed to prepare for subsequent procedures, may be the cause of this disparity.

Strengths of the study

This study offers some advantages of its own. First, all hospital surgical departments were considered. Second, the research tool was adjusted to fit the environment. Third, it was translated into Arabic so that everyone on the surgical team could understand it. Fourth, all levels of surgical teams cooperated. Fifth, the researcher rechecked the data after they were collected by skilled surgical team members.

Limitation of the study

The study was conducted in only one setting and in a brief period of time; therefore, the results might not be applicable to other settings throughout the country.

Conclusion

While checklists have the potential to enhance surgical safety, their effectiveness depends on how well they are implemented. The overall completeness of the checklist in the sign-in, time-out, and sign-out periods was satisfactory. Furthermore, healthcare professionals have recognized the usefulness of using the checklist
frequently during emergency cases. To promote more regular usage and enhance communication, additional training and focus on actual checklist utilization are recommended.

Recommendation

Checklists serve as a valuable tool to boost teamwork, enhance patient safety, and foster effective communication within a team. It's important for team members to actively utilize the checklist during their work routines to ensure consistency. It is also crucial to create awareness, specifically for new nursing and anesthetic staff, about the importance of using the checklist regularly. Furthermore, by conducting frequent audits to track checklist usage, providing ongoing training and refresher sessions to improve communication, compliance with the checklist can be enhanced. To encourage regular utilization of this valuable tool, it is recommended to prioritize training efforts and emphasize the significance of adhering to the checklist.

Declarations
