Abstract

Background: Coronavirus Disease 2019 (COVID-19) pandemic had an overwhelming impact on healthcare worldwide. Outstandingly, the aftermath on neoplastic patients is still largely unknown, and only isolated cases of COVID-19 during radiotherapy have been published. We will report the two-months experience of our Department, set in Lombardy “red-zone”.

Methods: data of 402 cancer patients undergoing active treatment from February 24 to April 24, 2020 were retrospectively reviewed; several indicators of the Department functioning were also analyzed.

Results: dedicated measures allowed an overall limited reduction of the workload. Decrease of radiotherapy treatment number reached 17%, while the number of administration of systemic treatment and follow up evaluations kept constant. Conversely, new treatment planning faced substantial decline. Considering the patients, infection rate was 3.23% (13/402) and mortality 1.24% (5/402). Median age of COVID-19 patients was 69.7 years, the large majority were male and smokers (84.6%); lung cancer was the most common tumor type (61.5%), 84.6% of subjects were stage III-IV and 92.3% had comorbidities. Remarkably, 92.3% of the cases were detected before March 24. Globally, only 2.5% of ongoing treatments were suspended due to suspect or confirmed COVID-19 and 46.2% of positive patients carried on radiotherapy without interruption. Considering only the last month, infection rate among patients undergoing treatment precipitated to 0.43% (1/232) and no new contagions were reported within our staff.

Conclusions: although mortality rate in COVID-19 cancer patients is elevated, our results support the feasibility and safety of continuing anticancer treatment during SARS-Cov-2 pandemic by endorsing consistent preventive measures.

Background

Italy has been the first western-world country massively hit by Coronavirus disease 19 (COVID-19). Since the first reported local transmission on 21st February 2020, the outbreak mainly involved northern area, with Lombardy standing out as the second region with most deaths worldwide after New York state, but with half of the population [1, 2]. Our Radiation Oncology Department is set in the main hospital of the city of Brescia, known for being the province with the second higher number of confirmed cases in Italy [3]. Measures to hinder the dissemination of the virus were considerably curbed by the complexity of its detection, as the clinical presentation of Covid-19 is heterogeneous and a large proportion of the patient is asymptomatic. The scenario is even more intricate in cancer patients, as manifestations of the tumor and side effects of the treatment might mimic COVID-19 [4, 5]. Although this pandemic massively spread worldwide, the impact on neoplastic patients is still largely unknown. Currently, only a few retrospective reports have been published, including a small number of subjects on active treatment and suggesting that cancer patients might be prone to develop severe presentations of COVID-19 [6]. In this period of uncertainty, these very preliminary data could induce physicians to abstain from life-saving treatments in fear of the risk of infection. As one of the main Radiation Oncology Departments of Lombardy, we will attempt to delineate a comprehensive picture of our experience.

Methods

Data of all the cancer patients who underwent anti-cancer treatments, including radiation therapy, chemotherapy and other systemic therapies at Brescia University Radiation Oncology Department from February 24 to April 24, 2020 were retrospectively analyzed. We also identified patients with a confirmed diagnosis of COVID-19, defined according to the WHO criteria, with a positive real-time polymerase chain-reaction (RT-PCR) assay for SARS-CoV-2 on a nasopharyngeal swab. Demographic, clinical and treatment characteristics were retrieved from the medical records and from our Institution’s archiving systems. Data regarding the workload of our four accelerators, the number of new treatment planning procedures and of the accesses to our Day Hospital for systemic treatment and the number of absences of our staff have been retrieved from our institutional registry.

Results

3.1 COVID-19 impact on the organization of the Department

Our Department is equipped with a treatment area with four linacs (two Elekta Synergy®, a tomotherapy equipment -Accuray Radixact®- and a Cyberknife®). Of note, Cyberknife® was recently installed and therefore its workload was already limited due to the ongoing process of implementation. Other facilities include an inpatient ward with 22 beds, a Day-Hospital with dedicated rooms for visits and administration of systemic therapies and a brachitherapy unit. Coping with COVID-19 required a profound reorganization with the aim to continue treatment administration. All the personnel was required to wear appropriate personal protective equipment (PPE): surgical masks and gloves through the whole shift and further protections (including FFP-2/3 respirators, waterproof gowns and cuff, face-shield or goggles and shoe-cover) in case of direct contact with suspect or RT-PCR positive patients. Staff members that reported direct contacts with positive or suspect cases or manifested fever or respiratory symptoms were monitored with repeated RT-PCR tests for SARS-Cov-2 on naso-pharyngeal swab.

Patients on active treatment underwent SARS-Cov-2 screening according to the same criteria; they were also guided with detailed instructions regarding social and hygienic rules and required to wear surgical masks and sanitize their hands when accessing the Department. Since the beginning of March, all the people accessing the hospital were screened for body temperature. In addition, we established a day time phone counseling service for cancer patients seeking medical advice; the attending physician was also responsible of the internal triage procedure, run in a dedicated room to evaluate the subjects with suggestive symptoms.

The treatment priority for each indication was evaluated on the characteristics of the patient and the disease, following general principles [7, 8] that were tailored on a case by case basis. Priority was given to treatments with curative intent and which effectiveness could be significantly affected by delay. All the

procedures that could be deferred without an outcome impairment were postponed. Prescription of palliative radiotherapy was shifted when possible towards modulation of analgesic or systemic treatment. Scheduled follow-up visits were replaced by telephone interviews whenever possible: reports of imaging and laboratory tests were transmitted by e-mail or fax or retrieved from our hospital's archiving system, examined and compared to previous evaluations by a physician that afterwards contacted the patient to ascertain his conditions and list a new appointment.

Radiation treatment of positive or symptomatic patients, accordingly to their clinical conditions, was performed on a dedicated linear accelerator (Synergy® 2), at the end of the shift to avoid contacts with other people, using the appropriate PPE and carefully sanitizing the room after each treatment.

Our ward went through a progressive transformation: at first some rooms with assigned nurses and facilities were arranged for isolation, as no rooms in COVID-19 dedicated wards were available during the epidemic peak. In fact, despite five wards of our Hospital were reallocated with this purpose, they were completely occupied due to the inflow of hundreds of patients. Subsequently, the increasing number of positive patients determined a complete conversion of our ward into a "COVID-ward". At peak, seven positive subjects occupied our rooms, while other patients necessitating hospitalization were transferred to other "clean" wards. Additional preventive measures were implemented: swabs were performed periodically to all our staff and to every patient requiring hospitalization before admission; visits from patients' relatives were forbidden. Since April 17 our ward returned "COVID-free", a condition maintained up to date (June 06).

3.2 Covid-19 Impact On The Workload Of The Department

The enforcement of the above mentioned procedures resulted in a relatively limited reduction the overall workload of our four linear accelerators. The number of radiotherapy sessions provided each day is represented in Table 1 and Fig. 1a: the maximum decrease of total treatment number reached 17% and later contracted to 11%. The accelerator dedicated to the treatment of COVID-19 positive or suspect patients suffered a somewhat greater decrease (about 20%) due to time consuming sanitizing procedures that approximately doubled the duration of each session. Conversely, planning of new treatments faced a remarkable reduction (about 50%) throughout the whole month of March due to postponement of deferrable treatments and the need to avoid overcrowding of the waiting rooms. The relative reduction of brachytherapy treatments was mainly due to the deferral of treatment of low risk prostate cancer, while integrated treatments were granted. The administration of systemic treatment did not suffer a significant decrease, with a stable number of about 40–50 weekly accesses and periodic slight deflections unrelated to COVID-19, mainly due to logistical reasons and different treatments' duration (Table 1, Fig. 1b). Scheduled follow-up visits were postponed or processed through telemedicine as stated above. An almost complete switch towards this modality allowed to maintain an overall stable number of follow up evaluations, as highlighted in Table 1.

Table 1

a) number of daily provided radiation treatments by week for each linear accelerator (Syn = Synergy®, Rdx = Radixact®, Cyber = Cyberknife®, COVID + = COVID-19 positive patients), total number of daily administered radiation treatments by week (Total) and weekly number of new treatments planning (Planning); number of weekly brachytherapy treatments (Brachy); number of weekly provided systemic treatment at our Day-Hospital (DH systemic t.), new patients first evaluation (admissions), in person follow up (FU i.p.), telemedicine follow up (Telemedicine FU) and total follow up evaluations (Total FU).

| 30 Mar – 3 Apr | 44 | 38 | 6 | 30 | 2 | 114 | 54 | 7 | 49 | 30 | 7 | 85 | 92 |
| 6–10 Apr | 46 | 33 | 4 | 29 | 1 | 109 | 82 | 10 | 43 | 25 | 10 | 88 | 98 |
| 13–17 Apr | 43 | 36 | 6 | 29 | 2 | 110 | 60 | 8 | 37 | 25 | 11 | 78 | 89 |
| 20–24 Apr | 48 | 35 | 2 | 31 | 3 | 117 | 66 | 14 | 45 | 27 | 15 | 87 | 102 |

Several of our patients considered discontinuation of ongoing life-saving treatments, frightened that hospital accesses could expose them to contagion: ten patients actually refused to start their treatment on the planned date, while no ongoing treatment was stopped for patient's decision.

3.3 Covid-19 Impact On The Staff

Characteristics of the impact of COVID-19 on our personnel are summarized in Table 2 and Fig. 1c. Our staff during the index period included a total of 87 professionals: 15 radiation oncologists, (of whom 5 temporarily employed), 17 radiation oncology trainees, 27 nurses, 22 radiation therapists and 6 physicists (4 full time and 2 part-time assigned to our Department). Nine symptomatic subjects received a positive naso-pharyngeal swab assay for SARS-Cov-2, three

tested positive while asymptomatic and seven displayed a distinctive clinical presentation with negative RT-PCR. It has to be noted that all the positive cases among our staff were reported between 2nd and 17th of March. Infection rate was 13.7% among the total staff, with comparable numbers for radiation oncologists, trainees, day-hospital nurses and radiation therapists. No cases were identified within physicists, while 33.3% of ward nurses tested positive. Symptoms were mild and managed with household isolation in almost all cases, with only our ward head-nurse requiring hospitalization for severe pneumonia. A relative shortage of personnel was evident from the second week of March to the first third of April. This required a temporary reallocation to our inpatient ward of three nurses from our day-hospital and of two nurses from the Oncology Department.

Table 2

number of available staff members for each week (W = ward; DH = day-hospital, R.T. = radiation therapists, hw = home working, R.O. = radiation oncologists; R.O.T.= radiation oncology trainees, total C-19 + = total of COVID-19 positive staff members) and percentage of absences of total staff. In the last lines, total number of units for each category and infection rates are reported.

| | Nurses (W) | Nurses (DH) | Nurses (total) | R. T. | Physicists (hw) | R. O. | R. O. T. | Total staff | Total C-19 + | % absences |

3.3 COVID-19 impact on the patients.

Of the 23 patients on active treatment with a suggestive clinical presentation, 13 tested positive and 10 negative for RT-PCR assay. Considering the index period (February 24 to April 24), 402 patients underwent active treatment at our Center, of whom 324 were administered radiotherapy or radio-chemotherapy and 78 only systemic treatments. Therefore, the infection rate among patients receiving active treatment was 3.23% and the mortality rate was 1.24% (5 deaths). Characteristics of the positive patients are outlined in Table 3 and Table 4. Median age was 69.7 years and the large majority of patients were male (84.6%), active or former smokers (84.6%) with an Eastern Cooperative Oncology Group Performance Status (ECOG-PS) of 0–1 (84.6%). The most common cancer type was Non-Small Cell Lung Cancer (NSCLC), totaling 61.5% of cases, followed by Head and Neck Squamous Cell Carcinoma (15.4%); 84.6% were stage III-IV. Almost all the subjects bore comorbidities, with 38.5% presenting three or more, mostly represented by cardiovascular diseases. Timeline of confirmed infections is illustrated in Fig. 1d. Remarkably, 12 of the 13 first positive tests were collected before March 24 and 4 of the 5 deaths occurred within March 16. While two of the deceased were on palliative treatment and already in bad general conditions (ECOG-PS 3), the other three were in initially fair conditions and receiving radical treatments for locally advanced disease. Of the other positive patients, six carried on radiotherapy (in two cases with hypofractionation of the remaining dose) without a break; a single treatment was definitively halted before the planned dose and one underwent a prolonged stop (due to admission to another hospital) and restarted RT 45 days later after dose replanning. Of the 10 patients with suggestive symptoms and a swab negative for SARS-Cov-2, two continued radiotherapy without interruption, three restarted it after a short delay (median of 4 days) and two were admitted to other hospitals with consequent prolonged discontinuation (over 30 days) that will require a new treatment planning; two adjuvant chemotherapy cycles have also been postponed. Suggestive imaging findings were identified on chest X-ray of COVID-19 positive patients in 84.6% of the cases and in all the chest CT-scans performed. All the positive cases were periodically evaluated also by the colleagues of infectious disease and anesthesiology departments and the majority was treated off-label with hydroxychloroquine (84.6%), antiviral drugs (84.6%) and azythromycin (69.2%); three patients also received tocilizumab (23.1%). Six patients (46.2%) developed severe disease, defined as necessity of high-flow supplemental oxygen. Supplemental oxygen was administered to 84.6% of patients and Continuous-Positive-Airway-Pressure to one patient. None of our patients was offered invasive ventilation, due to the absence of indication attributable to prognosis and general conditions in two cases and in three cases also due to the overwhelmingly high number of patients treated at

our hospital Intensive Care Unit during the outbreak peak, with consequent lack of available facilities. Six patients were discharged after full clinical recovery and negative RT-PCR on a naso-pharyngeal swab and two were transferred to other institutions at symptoms resolution, although still positive.

Table 3
 main COVID-19 positive patients' characteristics: ECOG = Eastern Cooperative Oncology Group; NSCLC = Non Small Cell Lung Cancer; SCC = Squamous Cell Carcinoma.

Discussion

Coronavirus-disease-2019 outbreak is currently generating an overwhelming burden for public health worldwide: up to date, 6,663,304 confirmed cases and 392,802 deaths were disclosed [9]. Oncology and radiation oncology practice have been affected as well, as the urgency of providing life-saving treatments could be undermined by the risk of infection. This generated a large body of recommendations, surveys and guidelines [7–8, 10–11]. Nevertheless, currently published clinical data are still limited, especially considering subjects on active treatment [12–19].

Previous series, including from 3 to 69 COVID-19 positive patients, reported an infection rate ranging from 0.79–2.7% among cancer patients and a mortality rate of 0–36% in infected subjects [13–23]. Only a fraction of the cases were receiving active treatment, mainly consisting of chemotherapy and immunotherapy or target therapy, and infection determined in almost all the cases treatment suspension [13–23].

In the first reports patients with ongoing radiotherapy were represented only by a total of three cases not described in detail [13, 14] and a 64 years old woman that, due to SARS-Cov-2 infection, suspended stereotactic radiotherapy for cT1bN0M0 NSCLC after 3 fractions (planned 55 Gy/5 in 5 fractions) [19].

Seven confirmed COVID-19 cases were identified in a prospective cohort at MD Anderson Radiation Oncology among 121 patients tested with RT-PCR [23]: six required hospitalization (four necessitating intensive care) and two (29%) died; three were undergoing RT at the time of COVID-19 diagnosis, of whom one deceased, and two needed treatment suspension (one temporary and one definitive). Of note, treatment was deferred or interrupted in 40 subjects while awaiting RT-PCR results.

The high rate of severe events described for patients on active treatment (reaching 83%) might raise concern and deter physicians to carry on anticancer therapy during COVID-19 pandemic, with the risk to impair its effectiveness. Nevertheless, it is at least premature to draw conclusions derived from such circumscribed data: increased COVID-19 severity in subjects under active treatment was reported only in two cohorts of respectively 4 and 6 patients [12, 13].

Contrasting conclusions were obtained in a recent prospective observational study performed in the United Kingdom amidst 800 patients with a diagnosis of cancer and symptomatic COVID-19: global mortality was 28% and significantly higher risk was observed for males, with advancing age and in presence of comorbidities such as hypertension and cardiovascular diseases [24]. Active treatments, including systemic therapy and radiotherapy, within 4 weeks before SARS-Cov-2 positive RT-PCR had no significant effect on mortality from COVID-19. Mortality rate was 23.7% among the 76 patients that recently received RT, but no detailed characteristics of radiation treatment, timing and possible delays or suspensions were reported.

We analyzed the data from 402 cancer patients that underwent anti-cancer treatments at our Department from February 24 to April 24, 2020. Infection rate in this population was 3.23% and mortality rate 1.24%. Although these numbers are higher than those calculated for the general population of Brescia province in the same period (respectively 1.01% and 0.19%) [25], the high proportion of risk factors for severe disease (age, comorbidities, male sex and smoking habit) [26–28] among our population must be considered. Additionally, the number of infections and deaths in the general population of our district could have been possibly gone under-detected as only a small fraction of it underwent RT-PCR assays and a large excess in overall mortality has been observed compared to previous years [29]. Among the 13 subjects with COVID-19 diagnosis confirmed by RT-PCR, mortality was 38.5%, higher than previously reported (range 0–36% in previous studies) [13–24]. This could be explained by unfavorable characteristics such as higher median age (range 56–68 years in previous studies [13–23], with similar mortality in the only report with higher median age [16]), high percentage of stage III-IV disease, predominance of male sex, smoking habit and significant comorbidities. Moreover, two of the deceased were already in critical conditions before being infected by COVID-19. The most common cancer type in our cohort was NSCLC, as in almost all previous reports (range 25–58.3%) with the highest reported proportion of 61.5%. Chest CT-scan confirmed its high sensitivity, as suggestive findings were reported in all the examinations performed. Differently from previous reports, chest radiograph assessed with a dedicated score [30–31] resulted positive in 84.6% of the cases. All the COVID-19 patients were treated in a hospital setting, the large majority received hydroxychloroquine (84.6%), antiviral drugs (84.6%), azithromycin (69.2%) and supplemental oxygen (84.6%). The lack of available facilities during the epidemic peak precluded the chance to provide invasive ventilation to our patients. Symptoms resolved in all the survived patients, six obtained RT-PCR assay clearance and two were still positive and were transferred to other institutions in good general conditions. Although practicing in one of the regions with the highest concentration of confirmed cases and deaths worldwide, COVID-19 outbreak led to the definitive or prolonged suspension of only 2.5% of the treatments ongoing during the index period, due to confirmed or highly suspect cases. This percentage drops to 1.5% considering only diagnosis confirmed by RT-PCR. Treatments were safely continued also in 46.2% of positive patients and 50% of patients with suggestive symptoms but negative RT-PCR. The global reduction of workload was limited: maximum decrease of radiotherapy sessions reached 17% and this reduction was limited to 11% at the end of index period. The administration of systemic treatments did not suffer a significant decrease and the number of follow up evaluations remained overall stable through an almost complete switch towards telemedicine modalities. By contrast, the procrastination of deferrable indications led to a conspicuous reduction of new treatment planning procedures throughout the whole month of March.

The experience of 17 Spanish centers reported in a recent paper [32] support the feasibility of continuing RT during COVID-19 pandemic. Fourteen of 1208 patients on active treatment developed COVID-19 confirmed by RT-PCR. The implementation of a multidisciplinary team and dedicated protocols allowed the completion of RT for 11 patients (78%); only one patient died due to complications of the infections. Unfortunately, no detailed characteristics of patients, disease and treatment were reported. Considering the staff, 8% of the members developed COVID-19 and had to quarantine.

The outbreak involved also our staff, with a combined infection rate of 13.7%, particularly elevated amid ward nurses (33.3%); in almost all the cases, symptoms were mild. The relative shortage of personnel did not affect our Department's activity but entailed a temporary reallocation of five nurses. Remarkably 12 of the 13 first positive tests from patients were collected before March 24, 4 of the 5 deaths occurred within March 16 and all the positive cases among our staff were identified before March 17. In the first phases, the extent of the outbreak in Italy was underestimated and according the availability of PPE and preventive measures was sub-optimal. This, combined with the considerable rate of transmission from asymptomatic subjects [33] and the incubation time [34], could justify the high incidence of infection in the initial two weeks. The strict application of a dedicated workflow and the constant adoption of adequate PPE [35–36] allowed us not only to contain and almost neutralize the diffusion of the infection, but also to carry on radiation therapy in patients positive for SARS-Cov-2 with mild or asymptomatic disease. The infection rate among patients undergoing treatment at our department outstandingly precipitated to 0.43% considering the period from March 25 to April 24 and no new contagion among our staff was observed in this time span. Our results corroborate the feasibility and safety of continuing anti-cancer treatment by endorsing consistent preventive measures, mitigating some concerns previously expressed [37–38]. We suggest to consider the risk of severe infection on a case-by-case basis and balance it with the effects generated by treatment delay or interruption. More than half of COVID-19 patients from our cohort had Stage III diseases amenable of curative treatment, which effectiveness could be heavily impaired by delay.

The limits of our study must be acknowledged. Although, to the best of our knowledge, this is the largest single-center series of COVID-19 patients ongoing radiation therapy, numbers are still small. A relatively high mortality rate was identified in this cohort, highlighting the need of a prompt diagnosis and an aggressive and timely treatment. As early detection of the infection is crucial, we advise to screen all the patients with RT-PCR on naso-pharyngeal swab before radiation therapy start [39]. Differential diagnosis with pneumonitis induced by immunotherapy or ionizing radiation should also be considered for differential diagnosis [40]. Social distancing and the rigorous adoption of PPE proved to be pivotal to restrain viral spread and should be uphold until complete resolution of the outbreak. As for our experience, the absolute number of COVID-19 positive patients requiring compelling treatment for each Institution is relatively low. The management of COVID-19 positive subjects could be therefore optimized with the implementation of dedicated pathways [41], preferentially defining a few specialized regional hub centers, where such patients could be centralized [42]. Fear of contagion should not divert from the urge to treat our patients, above all when a curative option is considered and if a delay could undermine its effectiveness. In this setting, the dread of a possible threat should not doom to a certain debacle.

Declarations

- **Ethical Approval and Consent to participate**

The study was performed according to ASST Spedali Civili di Brescia Ethic Committee principles. The study was conducted in agreement with the Declaration of Helsinki. All the patients signed a consent to share their clinical data and information for clinical studies.

- **Consent for publication**

All the patients signed a consent to share their clinical data and information for publication.

- **Availability of supporting data**

Data are stored according to our Institutional protocols and are available upon request.

- **Competing interests**

None to declare.

- **Funding**

None to declare.

• Authors' contributions

MB, AEG, SMM, FA, DT, NP and LT contributed substantially to the conception of the article; AEG, MB, ML, NB, AB, DT, DG, FB and LT contributed substantially to collection of clinical informations and data; MB, AEG, NP, LS, FA, LT, DT, DG, LM, GC and SMM contributed substantially to review of current literature; AEG, NP, FA, MB, LT, DG, DT and SMM contributed substantially to writing of the manuscript and data interpretation; MB, AEG, NP, DT, LT, FA, FB, LM and SMM contributed substantially to drafting and revisiting.

• Acknowledgements

We would like to thank the whole Radiation Oncology Department staff of the University - Spedali Civili Hospital, Brescia for their most generous and selfless commitment during this pandemic and for having contributed to the data collection:
