Abstract

Background: Information on the knowledge, management and ways of using food and medicinal plants by traditional populations, family farmers and Brazilian native population in the Amazon is essential to guarantee the sovereignty of these groups. The objective of this study was to evaluate the diversity, knowledge and ways of using non-conventional food and medicinal plants in traditional communities in a conservation unit in the Brazilian Amazon.

Methods: This study was conducted using semi-structured interviews applied to local respondents. Fifty-six residents were interviewed in 26 communities. The Indices of Use Value (UVI) and relative frequency of species citation (Fr) were evaluated; also, their diversity and equitability using the *Shannon- Wiener* (H') *Pielou* (J') indices, respectively. The species were listed according to their family, scientific name, popular names, categories of use, propagation environment, growth habit, medicinal indications, domestication status, production cycle and herbarium registration.

Results: A total of 269 species of both non-conventional food and medicinal plants were identified, distributed in 84 botanical families, 198 genera, in addition to 13 unidentified species. The Arecaceae and Lamiaceae families had the highest species richness (11 and 7, respectively). *Eryngium foetidum* L. (Apiaceae) and *Ipomoea potatoes* L. (Convolvulaceae) presented the highest relative citation frequencies (19.7 and 19.3, respectively) and the highest index of use value of the species (0.94 and 0.92, respectively). The *Shannon-Wiener* (H') and *Pielou* (J') diversity indices were considered high (5.02 and 0.9, respectively) when compared to other ethnobotanical works carried out in Brazil and in the Amazon.

Conclusions: A wide relationship of use was observed between the species under study and the population of this conservation area. In the environment in which these families are found, of geographical isolation and distance from urban centers, these species become, in many circumstances, the only food and medicinal resources, therefore, being fundamental to the sovereignty of these families.

Background

Brazil is a country of immense biodiversity, distributed throughout the biomes that occupy its territory. Among them, the Amazon stands out as the largest and the most preserved Brazilian biome, besides being the largest biodiversity reserve on the planet, occupying 49.29% of the national territory [1]. Its mega-biodiversity is currently estimated at around 2,500 tree species (representing one third of all tropical wood on the planet) and 30 thousand species of herbaceous plants and shrubs (out of a total of 100 thousand existing all over South America) [2]. This biome has a set of nature conservation units that are protected by law, such as the Extractive Reserves, where traditional populations, indigenous groups, *quilombolas*, riverside dwellers and family farmers live. These populations establish their forms of survival in line with and dependence on the available natural resources, especially non-conventional food plants and medicinal plants [3, 4].

It is a region of low demographic density, cut by countless rivers and lakes [5, 6], with an enormous coverage of tropical forest that, although has suffered an intense process of deforestation and forest degradation in the last decades, still preserves an extensive area of native forest [7]. This region is inhabited by populations in need of infrastructure and health and education services. The population has a low level of education besides being located in isolated places with difficult access and far from urban centers [8, 9], where people find in the forest resources, especially non-conventional and medicinal food plants, the main food and medicinal resources, respectively [10, 11].

Considering these specificities, these populations have developed a set of skills and tacit knowledge about the ways of using these forest resources over the years, adapting the survival strategies of the social groups living in these regions, whose knowledge has been tried, validated and transmitted through generations [12]. However, in the course of the last few years, due to an accelerated process of exploration of these areas, this knowledge has been lost [13], so it is necessary and urgent to carry out studies that investigate the potential of these plant species, which are associated with strategies for sovereignty, food security and therapeutically of these population groups [10, 14].

This study investigated the diversity, knowledge and ways of using non-conventional food plants and medicinal plants by traditional populations (collectors, family farmers, agro-collectors, *quilombolas*, indigenous and riverside inhabitants) in the Cajari River Extractive Reserve, state of Amapá, in the Brazilian Amazon. This conservation unit is located on the left bank of the Amazon River, an area cut by dozens of rivers and lakes, rich in plant biodiversity, fishing resources and wild animals that constitute the food base of the population residing in this conservation unit.

Methods

Study sites

The present study aimed to investigate the diversity, knowledge and ways of using non-conventional food plants and medicinal plants by traditional populations. Was carried out in a sustainable use conservation unit, the Rio Cajari Extractive Reserve (01°05'10"S e 51°46'36"W) (Fig. 1), which has an area of 532,397.20 hectares, and is located on the left bank and delta of the Amazon River, in the south of the State of Amapá. This unit is protected by law. It was created by Presidential Decree No. 99.145, of March 12, 1990 [15]. Its predominant vegetation is *terra firme* forests (the highest part of the unit), tidal flooded forests (intermediate part of the unit where floods occur and ebb from rivers) and flooded fields (next to the curves of rivers and streams, as well as rivers, streams and lakes).

The Cajari River Extractive Reserve covers the territory of three municipalities: Mazagão, Vitória do Jari and Laranjal do Jari, and has a population of 4,164 inhabitants [16]. It is located between the Maracá Agroextractive Settlement Project, at the BR 156 Highway (Macapá-Jari), the Jari Celulose Project and the Amazon River. Its population consists predominantly of family farmers who develop agroextractive activities (migratory farming of slash and burn agriculture, collection of fruits and vegetables in the forest and artisanal fishing); *quilombolas* whose inhabitants descended from slaves who came to the municipality of

Mazagão in the late 19th century; indigenous people of the Waiãpi ethnic group, riverside dwellers and extractivists who have the natural resources as their main source of survival.

The study was concentrated along three of the main rivers that make up the conservation unit, exactly where the communities where the collectors reside, in which the rivers Cajari, Muriacá and Amazonas (left bank) are located. In the Extractive Reserve there are communities, groups of several residences that are formed in strategic regions of the rivers, usually close to an inlet; in a place close to the mainland, favorable to small farms; with a vast abundance of certain products (Brazilian nuts, Acai), fishing resources; or even in strategic locations for navigation and local commerce, such as the mouth of rivers and *igarapes*.

The houses of the families can be seen in the communities. They are built of wood collected in the forest, covered with wood chips or asbestos tiles. The houses are built high above the level of the river and *igarapes* to avoid flooding during the Amazonian winter (rainy season from February to June). In most communities there is a level-I elementary school (up to the fifth grade), and in all communities there is the presence of religious institutions (Catholicism predominates, but with a marked presence of evangelical churches), elements of African and indigenous religions are also found there, showing strong religious syncretism.

Field trips and authorization for execution of the study

Four trips were made to the study area. Each trip lasted 12 to 15 days, from December 2016 to March 2017. These trips to the study area consisted of establishing an experience process with the community to conduct interviews and participate in their daily activities as well as the usage relationships with food and medicinal plants [17].

During the home visits, we sought to identify people recognized as owners of the ethnobotanical knowledge about medicinal and food plants [18]. To reach them, we counted with the help of key informants, such as agents of the unit's management body, leaders of local organizations, teachers of the unit's schools and some students from the Federal University of Amapá (UNIFAP) who are from RESEX Rio Cajari [19].

All the participants of this study were informed of its objective. They all agreed to participate and signed the Free and Informed Consent Form provided by the Ethics Committee in Research with Human Beings of the Federal University of Viçosa (CEP/ UFV), via Brazil Platform (Opinion number: 1.718.017).

Permissions for the study were obtained from the following agencies:

The research was registered in the National Genetic Heritage Management System (SisGen), which establishes criteria to access the genetic heritage and associated traditional knowledge, in accordance with the requirements of the biodiversity law (access registration number: A4DCD0D) [20].

The "Authorization for activities with a scientific purpose" was requested and obtained from the Biodiversity Authorization and Information System (SISBIO), an agency linked to the Ministry of the Environment (MMA), in order to obtain permission for the collection and transportation of biological material (authorization number: 55801-1).

The access to the conservation unit depended on authorization from the unit's managing body, the Chico Mendes Institute for Biodiversity Conservation (ICMBio), which issued the respective authorization, as well as the access to communities and their respective research informants were communicated and authorized by the organizations representing these residents, which were:

1. Association of Agroextractive Producers of the Middle and Low Cajari (ASS. CAJARI), in the Muriacá River region;
2. Association of Residents and Workers in Products of the Sociobiodiversity Chain of the Middle and Lower Cajari and Muriacá river active in RESEX Cajari (ACIOBIO), in the Cajari river region;
3. Association of Agroextractive Residents of the Cajari River (AMAEX-CA), in the Amazon River region.

Ethnobotanical data collection

Ethnobotanical information was collected through interviews with local experts who were appointed by the key-informants. In the interviews, semi-structured questionnaires containing pre-defined topics were applied, allowing the rise of new questions during the dialogue and the informants could spontaneously express their ideas about the use of plants for food and medicinal purposes [21].

Before starting the interviews, a pre-test of the interview script was carried out, with a group of five informants, in order to assess the clear understanding and precision of the terms, unfolding and order of questions, in addition to other information.

Plant species collection and identification

The collections of plant species were performed *in vivo*, with the participation of the informant, using the technique known as "guided tour" [22], in order to obtain the identification and more accurate information about the indicated species, following the methodological standards defined for ethnobotanical studies [23].

The species were registered by means of photographs and on records for the collection of botanical material.

Triplicates of each species were collected, then identified by means of comparison with samples from the Herbarium Collection of Amapá State (HAMAB), specialized bibliographies [24, 25] and consultation with botanical specialists. Subsequently, the exsiccates were herborized and incorporated into the collection of HAMAB, a faithful depository of samples of components of the Genetic Heritage of the Amazon, in the State of Amapá.

Data analysis

The homogeneity and diversity of food and medicinal species were assessed using the *Shannon-Wiener* Biological Diversity Index (H') and the *Pielou* Equitability Index (J') [26, 27]. These indices are used to assess the species richness in the studied area and the distribution of knowledge about plants among the research informants, respectively, were calculated for all food and medicinal plant species found in the present study, using the following equations:

Shannon-Wiener Biological Diversity Index (H'):

$$H' = -\sum p_i \log p_i,$$

Where:

$$P_i = n^i / N$$

n^i = number of citations per species

N = total number of citations

Pielou Equitability Index (J'):

$$J' = H' / H'_{\max}$$

Where:

H' = *Shannon-Wiener* Biological Diversity Index

H'_{\max} = (natural base logarithm) of the total number of the species

These indexes were compared with the indexes of similar studies carried out in the Brazilian Amazon and also in other regions, inside and outside Brazil.

The daily demand of species for food and medicinal use was evaluated, using the Use Value Index (IVU) [28]. This index is used to assess how well the species are known and used by the local population [29]. The IVU was obtained using the following equation:

$$IVU = \sum U / n$$

Where:

U = Number of citations of the species

n = Total number of research informants

The Relative Citation Frequency (Fr) indicates how much particular species stands out in relation to the rest of the others, and expresses how well the species is known [26]. This index was obtained using the following equation:

$$Fr = \sum (U \times 100) / N$$

U = Number of citations of the species

N = Number of species found in the study

The species were classified as non-conventional food, medicinal and dual-purpose (food and medicinal) [30]. The propagation environment (vegetable garden, orchard, forest, family farm and riparian forest) and growth habit (creeping, climbing, herbaceous, shrub and tree) of the species were observed and categorized [31], in addition to the forms of use and therapeutic indications in the case of medicinal plants [32].

A classification was made regarding the domestication status of these species in order to verify whether they are cultivated, or whether they propagate spontaneously [31], as well as their production cycles in annual, semi-perennial or perennial.

To compare the ethnobotanical indexes of this study with those of the academic literature, other works were searched in the Scientific Electronic Library Online (<http://www.scielo.org/php/index.php>), Scopus (<http://www.scopus.com/home.url>) and Web of Science databases (<https://clarivate.com/products/web-of-science/>).

Results And Discussion

Social-cultural characteristics

The survey of non-conventional and medicinal food species was performed along the three main rivers (Muriacá, Cajari and Amazonas) of the Cajari River Extractive Reserve.

The information was obtained from 56 informants, residing in 26 communities along these three rivers, which totaled 2,896 citations of food and medicinal vegetable species, are shown in Table 1.

The Tapereira *quilombola* community stood out with the largest number of informants, as it has historically accumulated an inheritance in the use of plant resources based on the knowledge inherited from their African ancestors [30]. This community contributed to the eminence of Cajari river regarding the greater number of informants. The communities of Conceição do Muriacá and Foz do Ajuruxi are the most populous within the unit. Both are located in the inlets of the Muriacá and Cajari rivers, and Ajuruxi and Amazonas, respectively. They have a larger population contingent, serving as a market center for products and people, with villages where schools, stores and health units are located, standing out among the other communities.

The number of informants per community is directly related to citations of plant species. The Tapereira community resulted in the highest number of species citations. However, the best citation average was generated in the Santana community as the informants in this community are familiar with a greater number of species of food and medicinal plants. The fact that the Tapereira and Santana communities had the highest number and average number of plant species has contributed to the fact that the Cajari River had the highest number of plant species mentioned (1215) and the average number of visited rivers (52.8 plant species / informant) (Table 1).

The methodological procedure adopted in the present study resulted in the finding of 56 plant specialists (37 women and 19 men), aged between 25 and 97 years old (Table 2), and with the following social occupations: farmers, extractivists, artisans, builders, fishermen, chestnut collectors, rubber tappers, carpenters, shamans and midwives.

According to the informants, the ethnobotanical knowledge about PANC and medicinal plants is concentrated in adults. Of the 56 informants, 31 are people aged between 25 and 59 years old, whose average age is 58.9 ± 14.6 . Although there are many elderly people, these results differ from other studies found in the literature in which they show that ethnobotanical knowledge about PANC and medicinal plants is concentrated in the elderly [31, 33, 34]. It is worth mentioning that the average age in the state of Amapá is 73.9 years [35], which is 20% higher than the average age of the informants in this study, thus, showing that this population, even though younger, has their ways of lives more dependent on the local plant resources.

The interviewees admitted that the young population of the unit are still interested in food and medicinal resources, although it differs from other studies on the subject [36], denominated Cultural Erosion by some authors [37]. However, it was possible to observe through the reports by the informants that in recent years, the phenomenon of urbanization in rural areas (access to traditionally urban goods and services, change in the income profile of some families), associated with the scarcity of some food resources (fish, and plants) has impacted the ways of life of local populations, gradually arousing greater interest in other food sources, and medicines in the pharmaceutical industry.

Table 2
Gender and age of the respondents and use category of the plants found in the Cajari River Extractivist Reserve in
Amazônia, Brazil.

Respondents	Communities	Gender		Category of use			Average of age \pm SD
		M	F	Med.	Food	Med./Food	
56	26	19 (34%)	37 (66%)	131 (48%)	72 (27%)	66 (25%)	58,9 \pm 14,6
(M) = Male; (F) = Female; (Med.) = Medicinal; (DP) = Standard Deviation.							

Regarding the gender of the survey respondents, there is a predominance of women (Table 2). They develop better knowledge about these plant species, as many of them are traditional cooks and some are midwives, who are responsible for preparing food and for the health of the family, while men are more explorers of the forest, involved in hunting and fishing, as observed in other works carried out with traditional communities [38, 39].

As for the category of use, ¼ of these species have a dual purpose (food and medicinal use). However, almost half of them are for medical use and the rest are for food use only, as observed in other studies conducted in Brazil [40], and in other countries in South America, Europe and Oceania [41, 42]. The relationship between the forms of use of these species occurs mainly because they are found in the same environment, propagated or cultivated using the same techniques. This relationship was established, above all, due to the geographic isolation in which these families are found, far from urban centers and without the possibility of income so to acquire other sources of food and medicines, therefore, these species have established themselves as the main resources, whose relationship is observed in other parts of Brazil and the world [43, 44].

Ethnobotanics data

A total of 269 plant species used for food and medicinal purposes were identified. They were distributed in 84 families and 198 botanical genera, resulting in a total of 2,896 citations. The species with the highest number of citations were *Eryngium foetidum* L. (Apiaceae) and *Ipomoea batatas* L. (Convolvulaceae), which were cited 53 and 52 times, respectively. *Eryngium foetidum* L. is a species of medicinal and food use. For therapeutic purposes, the tea boiled from its roots is indicated to fight parasites of the human organism, and as a food use, its leaves are cooked together with other foods. *Ipomoea batatas* L. is used for food purposes only, its tubers are cooked and served for breakfast (Table 3).

Table 3 contains information about the species identified in this study. The botanical families Arecaeae and Lamiaceae had the largest number of food and medicinal species, 19 and 17 species, respectively, with a predominance of species used for medicinal purposes. A situation also observed in other studies carried out with traditional populations in the Amazon, including studies carried out in rural communities in the municipality of Manacapuru, in Amazonas, Brazil [45]. In other communities in this municipality (Manacapuru/AM, Brazil), Costa, Mitja analyzed plant resources used by family farmers and observed a predominance of resources used for medicinal purposes [46].

In relation to the propagation environment of the species, it was found in the forest, vegetable gardens, orchards, Family farms and riparian forests (Table 3), but with predominance for those found in the forest (120 species) and in the vegetable gardens (65 species). This situation occurs mainly for two reasons. Firstly, because the study region is an environmental conservation unit in which plant extractions is the main source of income of the families, hence their strong relationship with the forest, as observed by Silva, Fantini, Shanley [47]. Secondly, because the communities where the families live are floodplain areas, which are flooded throughout the year, and like their residences, the gardens are also built with wood, or planted in canoes suspended from the ground, to prevent flooding and attack by animals that are raised loose, like buffalo. This form of cultivation in suspended beds has already been recorded in other studies with traditional populations and farmers in the Brazilian Amazon [45, 46].

It is observed a relationship between the propagation environment and the growth habit of these species, since among those found in the present study, 127 are of tree growth and 83 are herbaceous. The rest are distributed among those with shrub, climbing and creeping growth. Tree species propagate in upland forests, and herbaceous plants are grown in hanging gardens. Regarding the stage of domestication, the tree species are perennial native trees, found in the forest and riparian forests, and their food or medicinal resource are obtained spontaneously through collection. The other species are cultivated and grown in the suspended and cleared gardens, being species of annual and semi-perennial cycles. In the orchards are found the cultivated and spontaneous species.

Also, it is observed that the relationship between propagation environment, growth habit, stage of domestication and vegetative cycles is associated with the physiological characteristics of plants since there is no way to establish a tree species in a suspended garden, nor to cultivate a herbaceous in a shaded forest environment as observed in a study carried out on the use and knowledge of plants by traditional populations of the Tapajós National Forest (Santarém PA /

Brazil) [12]. The availability of these plant resources is associated with the social organization of families, since herbaceous species are required on a daily basis, and for this reason they are found in vegetable gardens and orchards, being easily accessible for women who deal with household activities [48]. The species located in the forest are seasonal, which makes them to be obtained, making them less required [48].

According to the informants' report, the number of PANC species and medicinal plants is decreasing and are found with more difficulties, mainly forest species with wood and food value, such as *Endopleura uchi* (Huber) Cuatrec, *Caryocar villosum* (Aubl.) Pers., *Bertholletia excelsa* H.B.K., *Tabebuia roseoalba* (Ridl.) Sandwith. This situation has occurred mainly due to the raise in the local population, which demanded the construction of more gardens and, consequently, increased the pressure on the river and the forest, but also due to the outbreaks of burning and deforestation that has frequently occurred within the unit. This is an aggravating factor, since many species are directly related to the food security of these families and there is no agronomic protocol, with propagation and management techniques that make it possible to replant seedlings.

The availability and seasonality of the species influence the social organization of families and communities [49]. This situation was observed in this study, since the forest provides many fruit food species, however they are only available during the Amazonian winter (February to June). After this period, the main food species are grown in the family farms (particularly the rhizomes and some herbaceous) during the Amazonian summer (July to December). The gardens are perennial and have food and medicinal species throughout the year. Medicinal resources such as leaves, seeds and bark are also available year-round in forests, riparian forests and orchards.

It was found in this study 138 plant species for food use. Of these, 96 are fruit species (the others are vegetables, seeds and rhizomes), and correspond to 69.5% of the food species found in here. Vegetables are consumed with food and represent only 6% of this percentage, which corroborates the fact that fruits are more present in the diet of traditional populations in the Amazon, as already observed in other studies [12, 46], together with cassava flour (*Manihot esculenta* Crantz.) and fish [50, 51]. Also, the consumption of vegetables is low among this population group, as highlighted by Adams, Murrieta, Sanches [52].

Among the species found in the study and available in Table 3, it was observed that some of them, from the families Acanthaceae and Amaranthaceae, has the same popular name of the trade name of some medicines sold by the pharmaceutical industry, such as the anador species (*Justicia pectoralis* var. *stenophylla* Leonard), *melhoral* (*Justicia pectoralis* Jacq.), Ampicillin (*Alternanthera tenella* Colla), penicillin (*Gomphrena arborescens* L.f.), terramycin (*Alternanthera brasiliana* (L.) Kuntze), cybalene (*Artemisia vulgaris* L.), paregoric elixir (*Ocimum selloi* Benth.), insulin (*Cissus sicyoides* L.), large vique (*Mentha spicata* L.) and small vique (*Mentha arvensis* L.). Other authors have already found similar to the one in which these home remedies are associated with names of industrialized medicines, usually prepared in the form of teas [53]. A possible explanation for the attribution of the name of industrialized remedies to many medicinal plants may be related to the influence of allopathic medicine in rural areas, in which the name given to these plants has something to do with the smell, taste or effect of an industrialized medicine [53, 54].

The informants reported the existence of some medicinal and food species that are toxic. In this case, they developed some techniques that resulted from the knowledge inherited from their parents. Two examples are cited, the first is the use of *Aristolochia cymbifera* Mart. & Zucc., a medicinal species indicated for stomachache and headaches. According to the informants, the ingestion of the raw leaf can cause nausea, vomiting and dizziness. In this case, the "poison" is eliminated through the decoction of the leaves. The second example, is the species *Solanum americanum* Mill., whose fruit is consumed as food, however it is only ingested when it reaches full maturity, defined by the dark color. If consumed before this stage of maturation, it can cause fever, headache and diarrhea.

Regarding the forms of use, particularly for food plant species, it was observed that fruit species are mostly consumed in its fresh form (*Endopleura uchi* (Huber) Cuatrec., *Bactris acanthocarpa* Mart.) and in some cases they are prepared as juices (*Oenocarpus bacaba* Mart., *Oenocarpus mapora* Karsten). Rhizome-producing species are cooked and usually consumed in the breakfast (*Dioscorea trifida* L.f., *Arracacia xanthorrhiza* Bancr.) and vegetables are cooked with other foods (*Eryngium foetidum* L., *Hibiscus sabdariffa* L.).

This survey did not identify the habit of preparing salads with vegetables. However, it was observed that some seeds are used as condiments (*Bixa orellana* L.), *paçoca* (*Sesamum orientale* L.) and consumed in fresh (*Bertholletia excelsa* HBK) and, finally, some of these species are consumed in the form of boiled teas (cooking), during breakfast (*Cymbopogon citratus* (DC.) Stapf, *Cinnamomum zeylanicum* Blume).

Regarding the forms of use of medicinal species by the population, there was also a diversity of forms of preparation. They are explained, as it follows:

Beverage

It consists in boiling dry barks of trees and vines. The boiling process takes around 1 hour. After boiling, it is allowed to cool to room temperature overnight and then it is consumed. It is usually indicated for pain, inflammation and different infections in the body. Another way to prepare the beverage is to expose the preparation (water + plant) to the sunlight for 10 to 15 days, until the beverage is completely fermented. The preparation of beverage from medicinal plants

is mentioned in several works in the academic literature. It has been even carried out by community members in the wake of a conservation unit in the Caatinga [53, 56].

Tree bark sauce

It is widely used for stomachache, diarrhea and ringworm (in this case, the use does not occur through ingestion, but by topical application). This practice is similar to making teas; however, it is used only with the bark of the trees, and the water is not boiled. It should be observed that the bark must be immediately removed from the plant and immersed in water, remaining long enough to color the water using the plant's natural dye, and then it is ingested [32].

Mixture

It is widely used for headache, dizziness, diarrhea, stroke, among other discomforts. It consists of mixing the species indicated for this type of discomfort, fermenting them in alcohol, then putting them in a bottle, and inhaling it. Another form of use for body aches is to massage the sore spot with the mixture. This method is similar to the *garrafada*, the difference is that the fermentation of the beverage occurs in alcohol, while the fermentation takes place in water, under boiling or at room temperature.

Bath (maceration): It is used mainly against flu and cold. They consist of mashing the leaves of the species indicated for this discomfort by hand, immersing them in water, and exposing them in dew overnight. The next morning, wash the head with the beverage. Another possibility for preparing the *baths*: it can be cooked, with the leaves mashed using the hands, boil them for approximately one hour, leave it in the dew overnight, and use it the next day. It is a form widely used in several regions in Brazil [32, 56].

Teas: It is used for medicinal and food purposes. Preparation: leaves or peels are immersed in water during boiling. Generally, medicinal teas are prepared with leaves of various species indicated for a certain discomfort, and in food teas, with one species. This is the form of use most practiced by rural populations, also known as decoction [53].

Syrup

It is called licker, usually indicated to cure the flu. It is prepared from an oil (*Carapa guianensis* Aubl.), using leaves of some medicinal plant indicated for flu and bee honey. Boil everything together for 30 minutes, then let it cool, and gradually take a spoon three times a day [53, 56].

Juice of the leaves and seeds

It consists of grinding the leaf or seed of the species indicated for a particular disease, and ingesting it. It is indicated for symptoms of diarrhea, intestinal parasites and anemia, etc. You can also place it on the site of discomfort when it comes to ringworm, ear pain, etc. This form of use of medicinal plants was observed in riverside communities in the municipality of Manacapuru, state of Amazonas, Brazil [45].

Tree milk

It is extracted from the stem of forest species for food and medicinal purposes [57]. In relation to food use, the milk is ingested. In a medical case (ulcer, gastritis, inflammation), it can be ingested or placed over the place where the discomfort occurs (vision problems, toothache, blood stasis, insect bites). It is noteworthy the use of this resource as medicinal to treat muscle strain [58].

Oil

It is used for food and medicinal purposes. It is generally used as a condiment in the preparation of food and frying. In medicinal use, it is ingested both fresh and in bottles. The oils are extracted from both the stem of forest species and fruits and seeds. Its use is quite common in popular medicine in the Brazilian Amazon [59].

Plant sap

It can be either the stem sap (*Montrichardia linifera* Schott., *Saccharum* spp. L.), or the leaves (*Cecropia pachytachya* Trécul). They are collected from the plant species and consumed immediately after it. It is indicated for problems in the spleen, gastritis, malaise and indisposition in the body [59].

Ethnobotanical indices

The *Shannon-Wiener* biological diversity index and the *Pielou* equitability index were equal to 5.02 and 0.90, respectively. According to Hammer, Haper, Ryan, these are considered high [60]. It was observed the high richness of species of food and medicinal plants in the region under study, and that the knowledge about the use of these species is widely distributed among users of these plant species. This high diversity of plants may be the result of the high ethnobotanical knowledge that traditional, *quilombola* and indigenous populations develop through a combination of African, Amerindian and European knowledge about plants [30].

The results found for the diversity and equitability indexes in this study are superior to those found by Silva, Tamashiro, Begossi in work carried out with traditional populations in the Amazon [61]. These authors found 425 plant species used for medicinal, food, construction, ritual and ornamental purposes, and obtained the *Shannon-Wiener* index equal to 4.71. Kainer, Duryea also in a study carried out on plant resources in a conservation unit similar to this study, but only with women, found 145 plant species used for medicinal, food, construction, ritual and ornamental purposes, and obtained the indices of *Shannon-Wiener* and *Pielou* equal to 4.8 and 0.97, respectively [62]. In this last work analyzed, the *Shannon-Wiener* index was lower than that of the present study, and the

Pielou index was higher due to the greater diversity of species. However, knowledge about the use of species was better distributed and less concentrated among informants.

There are works carried out in the Amazon and in other biomes in Brazil that show similar diversity and equitability indices, such as the one carried out by Amorozo, Gély who obtained *Shannon-Wiener* and *Pielou* indices equal to 5.07 and 0.94, respectively with 17 informants in an ethnobotanical survey carried out only on medicinal plants [63]. In addition, works carried out in other biomes in Brazil registered *Shannon-Wiener* and *Pielou* indexes more expressive than those already found [64, 65, 66].

The species *Eryngium foetidum* L. (Apiaceae) and *Ipomoea batatas* (L.) (Convolvulaceae) were the most cited by the informants (Table 4) in this study. Also, they obtained a relative citation frequency of 19.70 and 19.33, respectively. The fact that these species are the most cited means that they are the best known [31]. By observing the most cited species (Table 4), it is found that they are species grown close to the households, in domestic gardens or in the fields. They occur spontaneously in the orchards next to the residences. The fact that *Eryngium foetidum* L. (Apiaceae), for example, has a dual purpose of use (food and medicine), it can contribute to making it better known and demanded by the informants on a daily basis. These species occur significantly in other studies on food and medicinal resources in the Amazon region [45, 67] and other biomes in Brazil [68].

The Use Value Index of the species (Table 4) is ratified by the number of citations and the relative frequency of citations, that is, it is calculated considering the citations of the species by the number of informants in the research. The results show how much the species is demanded. The species with the highest relative frequency of citation will also be those with the highest indices of use value, that is, those most demanded by the feeding strategies and local phytotherapy of these informants on a daily basis [29].

It is worth noting that the higher the use value of these species, the greater the pressure of use upon them [69, 70]. In the specific case of this study, this analysis is very relevant, especially for the species found in the forest, whose reproduction process is more complex, and for most of them there is still no elaborated agronomic protocol.

Table 4

Relative frequency (Fr) and Value of Use Index (VUI) of the species of food and medicinal plants found in the Cajari River Extractive Reserve, Amazon, Brazil.

The other species found in the present study were mentioned only once, with Fr and IVU, equal to 0.37 and 0.02, respectively.

Conclusions

The study showed that the residents of the Cajari River Extractive Reserve use 269 plant species as food and/or medicinal products, associated with high diversity and equitability. These data reveal the large knowledge about the use of plants in this unit, which constitute a real socio-cultural heritage of these populations. One of the assets observed in the present study, which differs from others found in this segment, is the interest of the young people in these plants, despite the observation that such interest is decreasing and with a tendency to focus on women and adults and the elderly. This shows the need to register and disseminate the diversity and ways of using these resources, at the risk of losing such knowledge over time. It was also possible to verify the strong relationship of dependence of these populations, since the habitat of most of the species found in the study is the native and riparian forests. Finally, in the last years, the pressure of use on these resources has increased due to the rise in the population, the execution of gardens and fires, which urgently requires the protection, conservation and propagation of many species. These are directly related to the families' survival strategies, and for many of these species, there is still no agronomic protocol that makes it possible to replant them.

Declarations

Acknowledgments

The authors are especially grateful to the residents of Cajari River RESEX who participated in this study, for their welcoming and hospitality; the Graduate Program in Phytotechnics at the Federal University of Viçosa (UFV); to the Coordination for the Improvement of Higher Education Personnel (CAPES); to HAMAB taxonomists Patrick Cantuária and Tonny Medeiros for their valuable contributions to species identification.

Authors' contributions

GXPf and RHSS planned and coordinated the study; GXPf, AFR, AFM and WFP performed the fieldwork; GXPf, WLB and RHSS analyzed the data, discussed the results, wrote and reviewed the manuscript. All authors read and approved the final manuscript.

Funding

The study has been funded by National Council for Scientific and Technological Development (CNPq) (Edict No. 21/2016), Dean of Research and Graduate Studies at the Federal University of Amapá (PROPESPG/UNIFAP) (Edict No. 14/2017) and by Research Support Foundation of the State of Amapá (FAPEAP) (Edict No. 006/2017).

Availability of data and materials

The authors already included all data in the manuscript collected during the field surveys. The documented plant species were deposited at Herbarium Collection of Amapá State (HAMAB), Macapá, Amapá, Brazil.

Ethics approval and consent to participate

During field work, prior consent of the informants was taken conducting these studies. This was done to adhere to the ethical standards of community participation in scientific research.

Consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
