Abstract

Water, sanitation, and hygiene interventions significantly reduce health risks in low- and middle-income countries. Many rely on women for their success but the extent of women's engagement remains unclear.

We conducted a re-review of papers from two systematic reviews that assessed effectiveness of water, sanitation, and/or handwashing with soap interventions on diarrheal disease and acute respiratory infections to assess women's roles in WASH research and intervention activities (PROSPERO registration: CRD42022346360).

133 studies were included. Among studies that specified gender, women were the most targeted group for engagement in research (n = 91/132; 68.9%) and intervention (n = 49/120; 40.8%) activities. Reporting time burden for research (n = 1; 1%) and intervention activities (n = 3; 2.5%) was rare. All interventions were classified as gender-unequal (36.7%) or gender-blind (63.3%) according to the WHO Gender Responsiveness Assessment Scale, indicating exploitative engagement.

Women play a critical but instrumental role in advancing WASH, which requires change to enable, not hinder, gender equality.

Introduction

Water, sanitation, and hygiene (WASH) services are foundational to human health and wellbeing. Results from two recent systematic reviews found that WASH services can significantly reduce the risk of diarrhea and acute respiratory infections in low- and middle-income countries (LMICs). Recent disease burden estimates suggest that 1.4 million deaths and 74 million disability-adjusted life years were attributable to unsafe WASH in 2019. However, due to a paucity of evidence, these estimates do not account for multiple other health outcomes related to WASH, including bodily injury, violence, and stress, which are often of particular concern for women and girls. 4-7

In 2022, an estimated 27% of the global population (2.2 billion) lacked access to safely managed drinking water services, 43% (3.5 billion) to safely managed sanitation services, and 25% (2 billion) to basic hygiene services. Because women and girls play a central, and sometimes outsized, role in managing household WASH resources, these inadequate conditions place considerable burdens on them. Due to gender norms, women and girls often bear responsibility for household WASH: time-consuming and physically arduous activities like water fetching, latrine cleaning, and keeping children clean. While these activities may produce improvements in overall health, they can demand women's time and energy, limit opportunities and result in risks to their own health and safety. Further, they have the potential to perpetuate gender inequity.

Whilst these unpaid burdens and norms have been acknowledged, they also have been exploited by research and practice initiatives, ¹⁵ as women are often intentionally targeted by those delivering WASH

programs as key instruments for their success. Women have been trained to carry out water treatment, safe child feces management, and hand hygiene promotion. 12,17-19 Yet assessment of the extent of women's engagement in WASH programs and the impact of this engagement on their own health and wellbeing has been limited. A recent review of adoption of point-of-use chlorination for treating household drinking water found most studies deliberately targeted women to perform water treatment tasks, leveraging their household water management and caregiving roles. The time burden associated with this work was often reported to be a barrier to use but seldom quantified. 18 Similarly, women have been targeted to participate in research activities as part of largescale WASH evaluations to provide detailed data about family members' behaviors (e.g., defecation practices) 19 and health (e.g., diarrhea). 20-22 These examples point to the need for comprehensive assessment of the central part that women play in WASH research and practice.

Despite heavily involving women, rarely have WASH interventions and evaluations been designed and delivered to explicitly improve or even understand their impact on women's lives. WASH interventions should, however, be evaluated to understand if and how potential burdens and benefits from these interventions have been distributed, and if and how participants' engagement reinforces existing gender roles. While some WASH interventions, such as household water treatment, place demands on women, others could relieve them. For example, piped water systems or passive chlorination devices may not only reduce child illness, they also could eliminate the time and labor required to fetch and treat water and the time, financial, and psychosocial costs of caring for sick household members. Yet, these co-benefits are rarely assessed.²³

The aim of this re-review is to assess how women are engaged in WASH research and intervention activities. Through a re-review of the interventions designed to improve diarrheal disease and acute respiratory infection in LMICs, we: 1) identify the gender of the individual(s) targeted for research and intervention activities; 2) determine if time required for engagement was reported and, if so, compensated; 3) discern if additional intervention impacts specific to women were assessed; and 4) characterize intervention engagement overall and by intervention type using the WHO Gender Responsiveness Assessment Scale.²⁴

Methods

To understand women's engagement in research and intervention activities, we conducted a re-review of papers from two recent systematic reviews that assessed effectiveness of water, sanitation, and/or handwashing with soap interventions on diarrheal disease¹ and acute respiratory infections². The protocol is registered with PROSPERO (CRD42022346360). We report findings following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) criteria (Tables S1 & S2).

Inclusion criteria and eligibility

All papers included in the two previously published systematic reviews and published in English or Spanish were eligible for inclusion. The original search strategies, including eligibility criteria, for the two reviews, have been described previously^{1,2}.

Data extraction

To identify the gender of individuals targeted in research and intervention activities, two reviewers first independently extracted data on whether or not intervention and evaluation activities required individual-level participation from the target households/communities. Among studies that required individual-level participation, they identified the target demographic groups (women, men, men and/or women, girls, boys, girls and/or boys, other specified and/or unspecified individuals/populations). The dataset provides more detail on terms used and categorization assumptions (e.g., mother, caregiver, categorized as 'women') (appendix). They further extracted data on the time required for engagement and compensation provided (if reported), who reported the study's focal outcome (e.g., child diarrhea), if any additional intervention impacts specific to women, men, girls, or boys were assessed, and if the intervention activities included messages that involved shame or honor (e.g., establishing norms of "good" parenting).

To categorize engagement in intervention activities, we leveraged the WHO Gender Responsiveness Assessment Scale (GRAS)²⁴ for assessing gender responsiveness in health interventions, policies, and programs, and its elaboration by Pederson et al.²⁵ The WHO GRAS presents a spectrum of five gender approaches, from those that should be avoided (gender-unequal and gender-blind) to those that are more desirable (gender-sensitive, gender-specific, and gender-transformative). The modification by Pederson et al.²⁵ includes all five gender approaches and also shows how health programs, policies, and interventions along these various levels can either exploit, accommodate, or transform gender inequities, depending on how they are designed and delivered. Our slightly modified scale includes the definition of each approach as presented by the WHO²⁴ and Pederson et al.,²⁵ builds upon the definition of gender-unequal, and provides hypothetical WASH examples along the scale (Fig. 1).

We used this adapted figure as a tool to assess gender responsiveness in those interventions that required individual-level participation. Two reviewers independently reviewed intervention descriptions from the included studies and categorized them using the definitions noted in the figure. Inconsistencies in categorization were reconciled through discussion with a third team member. Interventions with multiple components can have different GRAS categories for each component, ²⁴ thus we categorized each water, sanitation, and/or hygiene component in an intervention separately, and provided an overall categorization of the intervention. We did not assess any non-WASH (e.g., nutrition) intervention components.

Analysis

We used R Studio v4.0.5 to generate descriptive statistics about which individuals were engaged in the research and interventions assessed, how they were engaged, what additional outcomes, if any, were evaluated, and how the interventions were categorized using the GRAS categories. We further organized

the GRAS data by the water, sanitation, and hygiene exposure scenarios presented by Wolf et al (2022). These exposure scenarios were informed by the definitions and exposure levels of the service ladders created by the WHO/UNICEF Joint Monitoring Programme for Water Supply, Sanitation and Hygiene (JMP) to assess progress against SDG targets 6.1 and 6.2, and were adapted based on available evidence. Wolf et al (2022) used the exposure scenarios to determine diarrhea risk at the various WASH service levels and concluded that higher service levels provided increased protection from diarrheal pathogens. We engaged the same exposure scenarios to determine if and how gender responsiveness varied at the different service levels.

All data will be made available upon publication in the appendix.

Role of the funding source

The funders of the study had no role in study design, data collection, analysis, interpretation, writing of the report, nor decision to publish.

Results

We assessed all 150 studies included in the two reviews; 14 were duplicates and 3 were excluded due to language, resulting in a final sample of 133 studies (See Flow Diagram Figure S1). Interventions focusing solely on drinking water (n = 64; 48.1%) or hygiene (n = 46; 34.6%) were the most common. The majority of studies took place in rural settings (n = 80; 60.2%) and in Asia (n = 51; 38.3%) and Africa (n = 43; 32.3%). Only 8 (6.0%) studies presented sex-disaggregated outcome data (Table 1). Table S3 presents a list of included studies and key characteristics.

Engagement in Research Activities

Individual-level participation in research activities was almost universal. Nearly all studies (n = 132; 99.2%) included at least one research activity that necessitated individual-level participation (Table 2). Of those, 92 (69.7%) studies targeted multiple groups to engage in research activities and over half (n = 89; 67.4%) did not clearly specify who was targeted for at least one research activity. Overall, among participants specified, women were the most targeted, followed by children. Women were reported to be targeted in 91 (68.9%) studies for research activities, and were the only group targeted in 14 (10.6%) studies. The most common research activities that women were engaged in included surveys (e.g., baseline, endline) (n = 63; 47.7%); diarrhea recall (independent of other surveys) (53; 40.2%); behavior/practice recall (independent of other surveys) (18; 13.6%) and observation (18; 13.6%) (Table S4). Children were targeted in 47 (35.6%) studies and were never the only group targeted. Their participation was most sought for biological specimens, including stool or rectal swabs (15; 11.4%) and sera samples (9; 6.8%). Only two (1.5%) studies reported targeting men for any research activities (survey, qualitative research).

The majority of studies depended on women to report the primary outcome (e.g., child diarrhea), yet few reported additional outcomes related to women's own health or co-benefits (if any) such as time savings. In 83 (63.4%) studies, women—specifically mothers—were noted to have reported the study's focal outcome. Most studies (111; 83.5%) reported additional outcomes other than diarrhea and/or ARI. These additional outcomes related mainly to children (n = 60; 54.1%); almost all (n = 59; 98.3%) reported on well-being outcomes (e.g., growth, parasitic infection, school absence) and 10 (16.7%) reported on program-related outcomes (e.g., hand hygiene, defecation behavior). Sixteen studies (14.4%) reported outcomes specific to women; three reported outcomes related to women's well-being (e.g., childcare hours saved, satisfaction with sanitation, water fetching time), while the rest focused on program-related compliance (e.g., hand hygiene, water treatment behaviors, etc.). Four (3.6%) studies reported outcomes specific to men; two focused on men's well-being (e.g., time fetching water, satisfaction with sanitation) and two on programmatic outcomes (e.g., defecation behaviors). Only one study (0.8%) comprehensively reported how much time was required for participants to engage in the research activities²⁶ and five (3.8%) studies compensated those engaged in research for their time (Table S3; also dataset).

Engagement in Intervention Activities

The majority of interventions required individual-level participation and most depended on women. One hundred twenty studies (90.2%) included at least one intervention activity that necessitated individual-level participation. Of those, 48 (40.0%) studies targeted multiple groups to engage in intervention activities but over half of the studies (n = 76; 63.3%) did not specify who was engaged. Among those that specified, women were the most targeted for intervention engagement, followed by children. Forty-nine (40.8%) studies targeted women for participation, including 21 (17.5%) studies that targeted only women. Women were the most targeted group for all water- (46; 38.3%), sanitation- (15; 12.5%), hygiene- (35; 29.2%), and health promotion-related (29; 24.2%) activities, which included WASH-related health education, water treatment, and child feces management, among other activities. Twenty (16.7%) intervention activities targeted children, including 2 (1.7%) that only targeted children. Children were most engaged in activities focused on hygiene practices and education. Only two (1.7%) studies reported targeting men for any intervention activities (hygiene-related health education; health promoter). Table S5 summarizes all intervention activities by populations engaged.

Despite the near ubiquitous need for individual-level participation in the WASH interventions assessed, reporting time burden or compensation was rare; only 3 (2.5%) reported the time burden of engaging in intervention activities and 13 (10.8%) reported providing compensation to individuals for their time (Table 2). From the information reported, ten (8.4%) interventions explicitly leveraged gender norms as an intentional part of their intervention; these referenced shame, honor, or upholding traditional values (for example, campaigns that promoted handwashing as practiced by 'good mothers'). Table S5 presents intervention activities by population engaged.

Characterization of Interventions using the WHO Gender Responsiveness Assessment Scale

We classified all interventions as either gender-unequal (36.7%) or gender-blind (63.7%) (Table 3), categorizations which are termed exploitative by WHO and which are by extension not recommended.

Of the 77 studies that included water interventions, 9 (11.7%) did not require any individual participation and among the remaining 68 that did, 24 (35.3%) are gender-unequal and 44 (64.7%) are gender-blind (Table 3). Table 4 presents examples of gender-unequal and gender-blind water intervention activities. Disaggregating by different levels of drinking water services, 57 (74.0%) involved point-of-use water treatment for sources off-premises, a low level of service according to the exposure scenario. Among these, 22 (38.6%) are categorized as gender-unequal and 35 (61.4%) as gender-blind. The one intervention that provided improved, on premises, continuous water supply—one of the higher levels of water service represented by the exposure scenario—was not evaluated using the GRA framework as it did not require individual-level involvement (Fig. 2).

Of the 18 studies that included sanitation interventions, five (27.8%) did not require any individual involvement and among the remaining 13 that did, all provided basic sanitation services without sewage connection with three (23.1%) categorized as gender-unequal and 10 (76.9%) as gender-blind. (See Table 4). The four interventions that provided basic sanitation with sewer connections were not evaluated using the GRA framework as they did not require individual-level involvement (Fig. 3a).

Of the 57 studies that included hygiene interventions, all required individual-level involvement and involved some type of hand hygiene promotion, though only 34 (59.6%) provided soap. Fewer interventions that provided soap were gender-unequal (n = 10; 29.4%) than were gender-blind (n = 24; 70.6%). Conversely, a greater proportion of the hand hygiene promotion interventions that did not provide soap were gender-unequal (n = 13; 56.5%) rather than gender-blind (n = 10; 43.5%) (Fig. 3b; Table 4).

Discussion

In this re-review of 133 studies from two systematic reviews assessing effectiveness of water, sanitation, and/or handwashing with soap interventions on diarrheal disease¹ and acute respiratory infections,² we evaluated the reported engagement of individuals in the evaluation and delivery of WASH interventions.

We find that, in many instances, the interventions that were the subject of these studies relied entirely on women as the agents of delivery and as the source of study data. WASH interventions were overwhelmingly gender-unequal or gender-blind and, therefore, classified as gender exploitative under the GRAS framework (Fig. 1). Any costs to women's own time or benefits to their own lives were rarely mentioned. Women appear to play a critical but purely instrumental role in advancing WASH. The often unacknowledged role of women in the evaluation and implementation of health-related WASH studies has several unintended, yet detrimental, consequences that require change for WASH to enable gender equality and not hinder it.

Perhaps the most insidious consequence of taking for free and for granted women's time and cooperation in WASH is that it cements existing and unequal gender norms. Maintaining family health,

which includes WASH tasks, is considered to be women's work, and women's labor is "understood" to be of low value. When WASH implementers and researchers not only avoid playing an equalizing role, but actively exploit gender-unequal roles, then existing inequalities are reproduced³² or even strengthened¹⁶. These observations—that women perform unpaid WASH labor and that this renders the research itself exploitative—are not new; this bias has been described since the early 1980s.^{33–35} Nonetheless, the exploitation of gender stereotypes and acceptance of numerous hours of unpaid labor by women has persisted. While occurring in both research and intervention delivery, the impact of engagement is likely quite different; the demand for women's unpaid labor in intervention delivery, in particular, could be sustained indefinitely or even scaled up if deemed effective at improving child health. Moving forward, WASH programs and interventions should be evaluated using the GRAS tool before implementation so those classified as exploitative can be redesigned or abandoned. Exploitative interventions should not be funded for evaluation.

Regardless of the effectiveness of the WASH interventions assessed, the full implementation costs have not been transparently acknowledged in evaluations or reflected in subsequent recommendations. Many WASH approaches, especially household-based approaches, are touted as "low-cost" by depending on women's "free" time and labor. These falsely low costs are routinely highlighted as a benefit for—and even a stipulation by—policy makers and donors, who often demand evidence of cost-effectiveness, put caps on the total costs allowed for an intervention, and restrict the types of allowable expenses (e.g., participant compensation). We acknowledge that the extent and nature of compensation must be context-specific so as not to place undue burdens on low-income communities and NGOs, and we recommend that WASH actors (i) budget appropriate compensation for those who shoulder the burdens of making these interventions "work," (ii) transparently report who is engaged, and (iii) rigorously evaluate participant time and opportunity costs.

The gender-unequal or gender-blind interventions were largely among interventions that represent lower levels of service, illuminating how these allegedly low-cost interventions not only demand "free" labor, but extract this labor to provide services or promote approaches that are often inferior. Interventions at the lowest service levels often emphasize behavior change, and as we and others have shown, most target women's behavior change. Yet, behavior change approaches are 'generally the least effective type of intervention'. Furthermore, 'the need to urge behavioral change is symptomatic of failure to establish contexts in which healthy choices are default actions. As a result, the women conscripted to perform (or enforce) WASH behaviors are likely living in the least enabling environments and therefore may have little chance for impact despite their efforts. Failed behavior change interventions tend to be ascribed to poor "compliance", which blames individuals—largely women—for intervention failure as opposed to the possible inappropriateness of the approach itself. Our data show that factors that shape individual ability to adopt interventions (e.g., time, finances)—which are useful to assess intervention appropriateness—were rarely documented. In contrast, the most common reported outcomes related to women were about their 'compliance' behaviors. Higher WASH service levels are critical for health and

for establishing contexts that enable healthy choices including relieving women's labor, saving energy costs and time, and lowering stress.

WASH provision at higher service levels does tend to require less household work, but cannot guarantee that women will not be burdened, or that their needs will be met. WASH approaches therefore need to be intentionally gender-sensitive, at a minimum. The JMP service ladders, which function as the benchmark by which to evaluate the quality of WASH services, are notably gender-blind³⁸ and therefore insufficient as the only benchmark. As an example, toilets can be categorized to be at the highest service level (safely managed) even if they lack a superstructure or a door because the ladder does not assess privacy. The global WASH community is already calling for a paradigm shift in how WASH services are delivered and evaluated.³⁹ Consistent with this call, we recommend that potential gender-related needs, burdens, and benefits are formally included when assessing the quality of WASH services, as well as in WASH evaluations when assessing their effectiveness in preventing disease.

A shift is also needed in how evaluations of WASH interventions are conceived, conducted and communicated to prevent further gender exploitation. As with intervention delivery, studies are not always explicit about who is engaged in research activities, women are routinely targeted, compensation is rare, and few report the time participation required. Women, in effect, act as unpaid research assistants. While there remain debates about research compensation⁴⁰, researchers and donors should be deliberate about time required from research participants and justify compensation decisions transparently.

These conclusions are limited by the information reported in the papers assessed, did not consider studies that may have been published elsewhere, excluded evaluations in languages other than English or Spanish, and may have a restricted sample because of the sources from which included studies were identified. Our re-review nonetheless takes a gender lens to prominent studies used to determine intervention effectiveness on key health outcomes. This lens should be considered when assessing the health impacts of WASH interventions. Specifically, women have been critical to evaluation research and intervention delivery and yet are often invisible and undervalued in the public health literature. Greater awareness and reflexivity are needed within WASH research and practice to elevate and value gender equity alongside health impacts.

- 1. For interventions or research activities listed as targeting 'Women or Men', these studies specifically indicated that either adult women or men were targeted.
- 2. Examples of 'Other Specified Individuals' targeted for research activities include: Daycare administrators and staff, teachers, key informants
- 3. For two studies, diagnostic tests or medical records were used to retrieve data on the focal outcome.

- 4. Studies only counted if information reported was clear and specific. Studies were considered to not have reported time if information provided was unclear, not specific enough, or not reported at all.
- 5. Examples of 'Other Populations' include daycare staff, household members, parents as a unit, households as a unit, and schools as a unit
- 6. Examples of 'Other Specified Individuals' targeted for intervention activities include: Daycare administrators and staff, teachers, field-based staff

^{1.} Examples of 'Other Specified Individuals' targeted for intervention activities include: Daycare administrators and staff, teachers, field-based staff

Table 4. Examples of gender-unequal and gender-blind water, sanitation, and hygiene intervention activities from included studies

	Gender unequal	Gender blind
Water	To reduce childhood diarrhea, a solar drinking water disinfection intervention was implemented. In intervention households, field workers visited biweekly for a year to emphasize the use of solar disinfection. Mothers and primary caregivers were specifically targeted to integrate the water treatment into their daily life. Other promotion activities occurred with the entire community and primary schools on a less frequent basis (i.e., monthly and three times, respectively). ²⁷	To prevent child diarrhea, a household biosand filter intervention was implemented. Intervention households received concrete biosand filters, education on how to use and maintain the filter, and a five-gallon narrow mouth bottle and base that allowed water to filter directly into the container for safe storage. Some intervention households had two follow-up visits post-installation. ²⁸
Sanitation	To reduce child stunting and anemia, independent and combined water, sanitation, and hygiene interventions were implemented. Women were enrolled in the study and scheduled to receive 15 behavior-change modules from village health workers over 12 months based on their 'treatment' group assignment (i.e., standard of care; infant and young child feeding; water, sanitation, and hygiene; infant and young child feeding plus water, sanitation, and hygiene). A sequential longitudinal intervention was also delivered, and reviewed modules with mothers monthly for six months. Household sanitation and hygiene infrastructure was also built and chlorine for water treatment was distributed. ²⁹	To prevent diarrhea, soil-transmitted helminth infection, and child malnutrition, India's Total Sanitation Campaign was delivered, combining social mobilization and a post-hoc latrine subsidy. The Government of India provided subsidies for the construction of latrines that met specified criteria in below-poverty-line households. Motivators in every village were trained to help mobilize the community as a whole. ³⁰
Hygiene	To prevent childhood infections and growth faltering, a community-based handwashing program that targeted mothers was implemented. In intervention communities, the program was launched at a community meeting that included an interactive educational session, discussion, and short play. Then, community motivators conducted home visits with mothers to encourage the establishment of new handwashing routines for six months. Daily visits were conducted for two weeks, and then decreased in frequency until the mothers were visited just once or twice a week. Group meetings were also held for mothers in each study area every two weeks to promote handwashing behaviors and distribute new bars of soap. ³¹	To prevent childhood diarrhea, an intervention to promote handwashing with soap after defecation and before preparing food, eating, and feeding a child was implemented. Field workers from local communities conducted weekly neighborhood meetings about handwashing for approximately one year, using slideshows, videotapes, and pamphlets. Field workers encouraged all household members who were old enough to understand to wash their hands at key times and provided soap to families, as needed. ³¹

Figures

Gender-unequal	Gender-blind	Gender-sensitive	Gender-specific	Gender-transformative
Perpetuates gender inequality by reinforcing unbalanced norms, roles, and relations	lgnores gender norms, roles, and relations	Acknowledges gender norms, roles, and relations, though does not address gender inequalities	Acknowledges women's and men's specific needs but does not address underlying causes of gender differences	Addresses the causes of gender- based health inequalities and works to transform harmful norms, roles, and relations
Often leads to one gender having more rights or opportunities than the other Places inequitable burden on women over men (or vice versa) ¹	Often reinforces gender-based discrimination Ignores differences in opportunities and resource allocation for women and men Often constructed based on the principle of being 'fair' by treating everyone the same	Indicates gender awareness, although no remedial action is developed	Intentionally targets and benefits a specific group of men or women to achieve certain policy or program goals or meet certain needs. Such policies often make it easier for women and men to fulfil duties that are ascribed to them based on their gender roles.	Objective is often to promote gender equality Includes strategies to foster progressive changes in power relations between women and men.
Examples: Intervention: Women household members specifically targeted to perform water filter cleaning and maintenance to enable program success. Men intentionally not engaged.	Example: Intervention: 'Household members' instructed to treat drinking water with chlorine prior to use, without specifying the gender of the person engaged.	Example: Intervention: Program staff acknowledge that girls and women bear responsibility for managing the household water, but intervention does not address this inequality in the household or community.	Example: Intervention: Program has an awareness campaign showing how women are not able to meet their personal water needs because of the competing needs of the household.	Example: Intervention: Program works simultaneously to improve access to water and shift gender norms such that women and men engage equally in household water acquisition and decision-making.
