44 **Abstract**

45 Handwashing is one of the vital public health measures to prevent COVID-19 pandemic from  
46 spread. However, water loss from excessive handwashing may put enormous pressure on the  
47 already overstretched groundwater resources and households' economic well-being. Therefore,  
48 this study aimed to determine the water loss during handwashing amid the COVID-19 pandemic  
49 with an emphasis on the waste of groundwater from essential hygiene activities at domestic scale.  
50 Sociodemographic data were collected using a web-based survey tool among 1980 participants  
51 and an experiment was conducted among 126 voluntarily interested participants to estimate the  
52 amount of water wasted during handwashing. A total of 80% of the participants washed their hands  
53 regularly after returning home from outside. About 57.27% participants generally did not turn off  
54 their tap when washing their hands. A single participant, who keeps his tap on throughout the  
55 handwashing process, wasted approximately 1.7 L of water per handwash and 14.9 L of water per  
56 day. Handwashing when a tap is on, raised the water loss at 13-fold during this pandemic compared  
57 to the non-pandemic situation which cost extra 224.95 BDT (2.65\$) per day for 1980 participants.  
58 A large number (57.27%) of people keep their faucet on during lathering hands with soap and  
59 scrubbing, thus wasting a considerable amount of water (1179% more compared to pre COVID-  
60 19 situation). The loss of water during handwashing is an alarming but less attentional issue.  
61 Behavioral change interventions are needed to aware people to shut off the faucet at periods when  
62 water is not being used.

75 **1. Introduction**

76 Hand hygiene is often considered as the synonymous of handwashing which is the most important  
77 factor in preventing nosocomial infections by preventing contact and fecal-oral transmission of  
78 pathogens (Boyce and Pittet, 2002; Widmer, 2000). Hand hygiene is an important public health  
79 measure (Burton et al., 2011; Tao et al., 2013) and it has long been recognized to be a convenient,  
80 effective, and also cost-effective mean of preventing infectious diseases (Tao et al., 2013). During  
81 the COVID-19 pandemic, frequent handwashing with soap and water was considered as one of the  
82 most effective measure to reduce the spread to infection (CDC, 2020; UNICEF, 2020; WHO,  
83 2020a). In addition to that, WHO and UNICEF also recommended switching the faucet/tap off  
84 while lathering hand with soap and scrubbing for at least 20 seconds to prevent the water loss  
85 (WHO, 2020b).

86 Many countries around the world, including Bangladesh utilize groundwater as the main source of  
87 drinking water and daily domestic activities. Evidence suggests that the frequency of handwashing  
88 increased during a pandemic situation (Park et al., 2010). The outbreak of Ebola in West Africa in  
89 2014-16 has also raised the demand for clean water for prevention and treatment (Conversation,  
90 2020). Therefore, the frequency of handwashing has also reported being increased during the co-  
91 current COVID-19 pandemic. The water demand raised by 20 to 25% in India during this COVID-  
92 19 pandemic due to the tap open during handwashing (Rohilla, 2020). Besides, a water sector  
93 official in Jordan, recently claimed that water demand has increased by 40% after the government  
94 ordered people to stay home as part of a nationwide curfew (Conversation, 2020).

95 This increase in demand will bring tremendous pressure on overstretched water resources to fill  
96 existing shortages in the water supply in a limited resource country like Bangladesh. This situation  
97 will be further worsened in the country in summer when sources of water supply run dry. Basically,  
98 all developments such as agricultural production, energy usage and economic activity involve  
99 water and/or affect water. But the water resource is not growing (Lundqvist, 2009). So, the loss of  
100 water during handwashing is a serious issue, but there is no previous study to evaluate water loss  
101 during handwashing globally. Therefore, the study aimed to determine the water loss during  
102 handwashing during the COVID-19 pandemic in Bangladesh.

103  
104  
105

## 106 **2. Methods**

### 107 ***2.1 Setting and participants***

108 A prospective cross-sectional web-based survey was conducted among the general population of  
109 Bangladesh to assess handwashing practices from May 21<sup>st</sup> to June 3<sup>rd</sup>, 2020. As a community-  
110 based face to face survey was not feasible during this COVID-19 pandemic situation, data was  
111 collected through online from all divisions (states) of Bangladesh. The authors distributed the  
112 survey link in all divisions of Bangladesh via social media among rural and urban people who use  
113 tap water or dug wells water. Snowball sampling method was used to recruit the participants. To  
114 improve the participation rate, reminder requests were sent thorough social media at 2-week  
115 intervals for a total of three times. The survey questionnaire was sent to more than 2500  
116 participants and 1980 of them from all the divisions of the country aged between 18 to 67 years  
117 completed the questionnaire. Eligibility criteria included the ability to read Bangla, residence in  
118 Bangladesh during the pandemic, and having access to the internet.

### 119 ***2.2 Data collection***

120 A survey tool was developed considering the regular pattern of handwashing practice and facility  
121 during the COVID-19 pandemic. The survey consisted of 14-close ended queries, which took  
122 about 3-4 minutes to finish. Sociodemographic data were collected on age, gender, educational  
123 status, location of residence. Besides that, the survey included questions on the frequency of  
124 handwashing, duration of lathering hand with soap and, scrubbing, whether they keep their faucet  
125 on or off during the lathering and scrubbing time.

126 The survey tool was piloted with a small online user group to test its clarity & consistency. The  
127 survey included a short overview of the study context, purpose, procedures, confidentiality  
128 agreement, and consent. This study complied with the most recent revision of the Helsinki  
129 Declaration (Williams, 2008) and followed the Checklist for Reporting Results of Internet E-  
130 Surveys (CHERRIES) guidelines (Eysenbach, 2004). Descriptive statistics were performed to  
131 define the fundamental characteristics of the data in the participants.

### 132 ***2.3 Procedure***

133 The average duration of lathering hand with soap and scrubbing was 17.95 seconds among the  
134 participants who usually keep their tap on throughout the handwashing process. An experiment  
135 was designed to estimate the amount of water wasted during that time. We invited 1134  
136 participants (57.27% of total participants) who did not shut off tap during handwashing to attend

137 the experiment voluntarily. A total of 126 participants (6.36% of total participants) among them  
138 agreed and participated in the experiment session from their house and each used 1 domicile  
139 handwashing faucet. The participants' inclusion criteria for the experiment of determining flow  
140 rate was to have the experimental tools such as stopwatch, milliliter jug etc. All the participant  
141 took part in this experiment were trained through online video conference. We divided them into  
142 14 groups, with nine participants in each group during the training session. Each participant used  
143 one faucet from his/her home and took part in 3 experiments at three different speeds of the faucet.  
144 For the better measurement of flow rate a total of 378 experiments were conducted setting the  
145 faucet at minimum (average = 39.41 mL/s; 126 experiments), medium (average= 84.16mL/s; 126  
146 experiments), and maximum speed (average = 161.33 mL/s; 126 experiments) arbitrarily. The flow  
147 rate is the volume of water (mL) per unit time (s) which flows through area of tap. Then water was  
148 collected in a water bottle marked with milliliter measurement. Participants counted and noted the  
149 time in seconds required to fill 1 liter of water for each experiment. Then amount of loosed water  
150 was calculated for 17.95 seconds (Table-2). The test procedure was based on Green Venture  
151 website: how to conduct a flow rate test, 2007 (Venture, 2007). This test procedure was also used  
152 in a previous study in China for determining the flow rate of water (Lu and Smout, 2008).

#### 153 ***2.4 Data analysis***

154 Descriptive statistics were calculated for sociodemographic characteristics. Experimental data  
155 were calculated using Excel 2013. Statistical analyses were performed using SPSS version 24  
156 (IBM SPSS Statistics, New York, United States).

#### 157 ***2.5 Ethics***

158 The research protocol was reviewed and approved by the Research Ethical Committee (REC) of  
159 the Department of Food Microbiology, Patuakhali Science and Technology University,  
160 Bangladesh (Approval No: FMB:29/05/2020:06).

### 161 **3. Results and discussion**

#### 162 ***3.1 Demographic information***

163 Table 1 represents the characteristics of the participants. Of the 1980 participants, 55% were male,  
164 29% were employers and 35% were graduates. More than 27% participants only completed their  
165 10<sup>th</sup> class or less. Although most of the respondents were from the Dhaka division (19.09 %), also  
166 respondents from all 8 divisions of the country participated in the study.

167

168 **3.2 Handwashing practice during COVID-19 pandemic**

169 Regular handwashing practice after returning home from outside was 77.9% during the pandemic.  
170 This finding is lower than the study in Bangladesh by Hauque et al. (2020) (95.45%) and Wadood  
171 et al. (2020) (89.5%). In contrast, regular handwashing practice after sneezing was poor  
172 (37.1%). During the COVID-19 pandemic, 88.4% participants washed their hands more compared  
173 to the non-pandemic situation as mentioned/stated by the participants. The average number of  
174 handwashing practices per day among the participants was 8.93( $\pm$ 5.86 SD). 82.52% of the  
175 participants use manual tap regularly for handwashing. The average duration of lathering hand  
176 with soap and scrubbing was 17.73 seconds per time among all the participants (Table 1).

177 **3.3 Water waste due to leaving the faucet on while lathering and scrubbing the hand with soap**

178 Of all the respondents, 57.27% reported that they keep their faucet on during lathering hand with  
179 soap and scrubbing. Among those who keep their tap on throughout the handwashing process, the  
180 average duration of lathering hand with soap and scrubbing was 17.95 and 4.39 seconds and the  
181 average frequency of handwashing was 8.73 and 2.79 times in a day during and before the COVID-  
182 19 pandemic. To put Table 2 into perspective, a single handwash wasted 1704.744 mL of water  
183 and 14882.415 mL of water in a day by a single participant during the COVID-19 pandemic  
184 whereas only 416.92 mL and 1163.20 mL of water was lost by a single handwash and a day  
185 respectively before the pandemic situation. Then if we calculate this water loss for 1134  
186 participants who keep their faucet on during handwashing, it will be 1179% or 12.79 times of  
187 (16876 L vs 1319 L) of water loss per day when we had only 1980 participants during this  
188 pandemic than the non-pandemic situation. 1134 participant's loss extra 15557 L of water during  
189 this pandemic for hand washing purpose which cost extra 224.95 BDT per day (14.46 BDT/per  
190 unit) (bdnews24.com, 2020). Muhit stated that enormous economic losses have occurred in  
191 Bangladesh every year due to poor sanitation and water supply, and this economic loss could  
192 increase due to the loss of water during hand washing in COVID-19.

193 **3.4 Limitation**

194 The speed of the tap was set by the judgment of the experimenter. The number of participants for  
195 the experiment was not large enough but from all divisions. Furthermore, we were unable to reach  
196 those participants who do not have an internet connection and throughout the experiment and we  
197 were unable to observe the participants, so the study is not without some errors. We had no better  
198 solution during the country wide lock-down situation. However, it still gives a reasonable

199 representation and we suggest a large-scale study with economic evaluation regarding the water  
200 loss.

#### 201 **4. Conclusion and recommendation**

202 While lathering hands with soap and scrubbing, a large number of people keep their faucet on,  
203 thereby wasting 1179% of water during this pandemic compared to the non-pandemic situation.  
204 The water loss during handwashing is too much not to worry about. The water and economic loss  
205 can be mitigated by good practice. One of the first things that we need to address is to minimize  
206 the speed of faucet during handwashing. That would save 140% of water by them who keep their  
207 faucet on during handwashing (57.27%) at least without relying on individual behaviors. It is also  
208 recommended to use push taps that automatically switch off after a period or sensor taps that are  
209 programmed to automatically turn on when hands are under the spout and immediately stop when  
210 the hands are taken away from the tap. Furthermore, behavioral change interventions are needed  
211 to make people aware in Bangladesh and similar low income countries to shut off the faucet at  
212 periods when water is not being used considering the limited water resources and respective  
213 potential stress on economics relevance to the loss. However, from a policy point of view, it is  
214 important to know how much the losses affect both the water supplies and the economic status in  
215 order to find an effective intervention. So further studies are required not only in Bangladesh but  
216 also worldwide. New findings of this study will benefit for future research to comprehensively  
217 assess the economic impact associated with the water loss on developed and developing countries  
218 due to new hygiene rules and regulations imposed during the COVID-19 outbreak.
