# Abstract

**Background:** This study evaluated the impact of multifaceted NPS MedicineWise programs conducted in 2009 and 2015 that targeted general practitioners (GPs) to reduce unnecessary prescribing of proton pump inhibitors (PPIs). **Methods:** Time series analyses was conducted of the dispensing rates of concessional PPI scripts between January 2006 and June 2016 using the Pharmaceutical Benefits Scheme (PBS) and Medicare Benefits Schedule (MBS) databases in Australia. Participants were GPs with dispensed PPI prescriptions to concessional patients between January 2006 and June 2016. The interventions were national NPS MedicineWise PPI educational programs in 2009 and 2015 delivered to all practising GPs in Australia. The 2015 intervention coincided with the release of Choosing Wisely Australia recommendations from the Royal Australian College of General Practitioners (RACGP). **Outcome measures** included monthly dispensing rates of standard and low strength PPIs prescribed by GPs among concessional patients in Australia. **Results :** Following the 2009 NPS MedicineWise program we observed a 6.7% reduction in the expected dispensing rate of standard strength PPIs among concessional patients between January 2006 and March 2015, and a total 8.6% reduction by June 2016 following the launch of the 2015 program. We observed a significant increase of 5.6% in the dispensing rate of low strength PPIs among concessional patients between April 2009 and March 2015, and no significant change in trend following the 2015 program. **Conclusions:** The NPS MedicineWise programs were associated with reductions in the dispensing rate of standard strength PPIs, and with an increase in the dispensing rate of low-strength PPIs by June 2016 although a causal relation was not confirmed. Although the rate of standard strength PPI prescribing is declining, these formulations still constitute the majority of PPIs used in Australia. Regular interventions to sustain and improve PPI management by GPs may be warranted.

## Background

Proton pump inhibitors (PPIs) are used to treat symptoms of gastro-oesophageal reflux disease (GORD), peptic ulcer disease, functional dyspepsia, Barrett’s oesophagus, and oesophagitis [1-3]. Clinical guidelines recommend that patients receive treatment for 4 to 8 weeks on standard strength PPIs and step down to a lower strength or discontinue treatment thereafter. A limited number of indications may require ongoing maintenance treatment [1, 4]. Despite these recommendations, there is growing evidence that PPIs are being inappropriately prescribed in contemporary practice, leading to overuse in both primary care and hospital settings [5-7]. In Australia PPI usage increased from 44.0 defined daily doses (DDDs) per 1000 population in 2000 to 77.5 in 2015 [8], and “standard” strength formulations, the highest strengths of each PPI medicine available (Table 1), constitute the majority of dispensed PPI treatment [9].

Table 1. PBS item codes used in the analysis of the NPS MedicineWise programs

Drug name	Strength	PBS item numbers
Esomeprazole	Standard strength*	8601Q
	Low strength*	8600P, 8886Q
Lansoprazole	Standard strength	2240X, 2241Y, 8528W, 8529X, 8949B, 8950C, 9477T, 9478W
	Low strength	8198L, 9331D
Omeprazole	Standard strength	1326T, 1327W, 8331L, 8333N, 8776X, 8777Y, 9109K, 9110L
	Low strength	8232G, 8332M
Pantoprazole	Standard strength	8007K, 8008L, 9423Y, 9424B
	Low strength	8399C
Rabeprazole	Standard strength	8508T, 8509W
	Low strength	8507R

\* There is no PBS-subsidised “low” strength formulation for esomeprazole. For the purposes of our analyses, we considered dispensings of the highest available strength esomeprazole (“high”; PBS item number 8601Q) as a standard strength PPI, and the lowest available strength esomeprazole (“standard”; PBS Item numbers 8600P & 8886Q) as a low strength PPI.

While PPIs are generally well tolerated, their use has been linked to an increased risk of several adverse outcomes [10-15]. In the past decade, initiatives such as educational programs conducted by NPS MedicineWise and recommendations by Choosing Wisely Australia [1, 16, 17] have been launched, with the aim of improving the quality use of PPI medicines and reducing the risk of PPI-related adverse outcomes. The Choosing Wisely program is a physician-led initiative that aims to encourage discussions between physicians and patients around practices that provide little value or may unnecessarily harm patients [16, 18]. In Australia, the program is facilitated by NPS MedicineWise, a national, not-for-profit organisation seeking to improve the quality use of medicines and medical tests in Australia through educational campaigns that target general practitioners (GPs), pharmacists, other health professionals and consumers.

In 2009 and 2015, NPS MedicineWise launched two multifaceted programs targeting GPs with messages about the quality prescribing of PPIs [19, 20]. Among other aspects, these programs promoted the appropriate use of step-down PPI treatment approaches. The aim of this study was to evaluate the impact of these interventions on dispensing rates of standard and low strength PPIs across Australia.

Terminology for PPI dose strength has changed from highest, high and low to high, standard and low since 1 May 2019 [21]. See Table 2 for further information.

Table 2: PPI strength categories before and after 1 May 2019

Medicine	Before 1 May 2019	After 1 May 2019
Esomeprazole 40 mg	Highest dose	High dose
Esomeprazole 20 mg	High dose	Standard dose
Lansoprazole 30 mg	High dose	Standard dose
Omeprazole 20 mg	High dose	Standard dose
Pantoprazole 40 mg	High dose	Standard dose
Rabeprazole 20 mg	High dose	Standard dose
Lansoprazole 15 mg	Low dose	Low dose
Omeprazole 10 mg	Low dose	Low dose
Pantoprazole 20 mg	Low dose	Low dose
Rabeprazole 10 mg	Low dose	Low dose

For simplicity we included the Esomeprazole 40 mg high dose as a standard dose and the Esomeprazole 20 mg standard dose as low dose for our analysis.

## Methods

### Description of the interventions

The April 2009 and April 2015 NPS MedicineWise PPI programs sought to provide and reinforce evidence-based recommendations to guide GPs in the appropriate primary care management of GORD, and to promote dialogue between GPs and patients about the relative benefits, risks, harms and costs of treatments. The programs included a review of recent safety updates from the Australian Therapeutic Goods Administration and tools for GPs to facilitate step-down PPI therapy in patients whose reflux symptoms were well-controlled [19].

GPs were also provided with feedback detailing their prescribing behaviours during the calendar years preceding each intervention (2008 and 2014). This feedback took the form of an individualised report sent to all registered and practicing GPs in Australia. The report used national medicines dispensing records from the Pharmaceutical Benefits Scheme (PBS) to summarise all PPI medicines prescribed by each GP, and compared their prescribing of each these medicines that of all other GPs in Australia. The report also highlighted how their prescribing aligned with best practice recommendations. This feedback was provided to approximately 20,000 GPs in 2009 and 24,000 GPs in 2015. The reports included the number of PPI prescriptions dispensed each month, the strengths of the prescribed PPIs, the cost of the prescribed PPIs, and the number of each doctor's patients estimated to be receiving long-term PPI treatment. Long-term PPI treatment was defined as having six or more PPI prescriptions dispensed.

In 2009 and 2015, these feedback reports were followed by a clinical audit and a case study for a sample of GPs who had received the reports. See Table 3 for the details and the reach of each of these aspects of the interventions.

Table 3: NPS MedicineWise interventions targeting PPI prescribing in Australia.

Intervention	Date	Details	Number GPs reached	
			2009	2015
PBS feedback	2009 and 2015	A personalised prescribing report was sent to registered practicing GPs in Australia. The distribution of feedback reports was coordinated with the Department of Human Services by using PBS data.	19,790	24,188
Case study	2009 and 2015	The educational activity explored how to manage a new PPI therapy according to best practice recommendations and it provided GP participants with immediate information on how their prescribing compared with their peers	169	397
Clinical Audit	2009 and 2015	GPs review their current prescribing practice for their patients compared with current best practice guidelines	1590	687

The key recommendations to GPs in the NPS MedicineWise programs in 2009 and 2015 were:

- Review all patients currently being treated with PPIs
- Confirm that the indication for treatment remains, evaluate whether the strength and frequency of PPI dosing can be reduced, and evaluate if PPI therapy can be discontinued
- Encourage lifestyle modifications and review the concomitant use of medicines that may exacerbate symptoms
- Decrease PPI treatment to low strength or intermittent, symptom-driven therapy once symptoms are controlled
- Always discuss the expected duration of treatment and have a plan for stepping down or discontinuing treatment when PPI treatment is initiated.

## Setting and data

Australia maintains a universal healthcare system entitling all citizens and permanent residents to subsidised medicines through the PBS and subsidised outpatient medical services through the Medicare Benefits Schedule. The Australian Government Department of Human Services (DHS), which is the administering body for the PBS and MBS, supplied summary data of monthly dispensing records of PPI medicines subsidised through the PBS, prescribed by a GP, for each GP; and monthly records of every medical service [22] billed to the government by each GP in Australia from January 2006 through to June 2016. GPs were registered general practitioners, trainees and non-vocationally recognised doctors. The DHS generated a unique identifier code for each GP in the data and this code allowed us to link dispensing and services data. Consent was sought from and provided by the DHS for this study.

PBS data capture prescription medicine dispensing that has resulted in a subsidy paid by the PBS; the data do not capture dispensing of medicines priced below the PBS co-payment threshold or medicines dispensed privately. The price of many PPI medicines is below the general PBS co-payment threshold (range: \$29.50 – \$38.30 between 2006 and 2016) but above the concessional PBS co-payment threshold (range: \$4.70 - \$6.20 between 2006 and 2016). To ensure complete ascertainment of PPIs dispensed during the study period, we restricted our analyses to concessional beneficiaries [23].

## Measures

As actual GP prescribing records are not available in our dispensing data, we examined the impact of the NPS MedicineWise interventions on the rate of dispensed PPI prescriptions issued by GPs as a surrogate measure of GP prescribing. Our outcome measures were constructed as the monthly number of standard and low strength PPIs (Table 1) dispensed through the PBS (numerators) per 1,000 reimbursable GP consultations (denominator) [24, 25]. In the case of esomeprazole, the only PBS-subsidised strengths available in Australia are classified as “high” and “standard” strength. As discussed previously, for the purpose of our analyses, we considered dispensing’s of the highest available strength esomeprazole (“high”) as a standard strength PPI, and the lowest available strength esomeprazole (“standard”) as a low strength PPI (Table 2).

## Statistical analysis

We used time series intervention models with an autoregressive residual process to analyse the dispensing rate of standard and low strength PPIs separately. We adjusted our data seasonally to account for the well-known “stockpiling” phenomenon that results in increased dispensing of many medicines subsidised through the PBS towards the end of each calendar year, and subsequent reduced dispensing during the following January and February [23]. We conducted our analyses using the seasonally adjusted data but added the unadjusted data series to the final graphic presentations.

We used two separate change-in-trend variables to represent the NPS MedicineWise interventions in 2009 and 2015. We hypothesised that the impact of the 2009 intervention would diminish with time and included a decay term for the 2009 program in our models to test this hypothesis. If the estimate of a decay effect was not significant, we set the decay parameter to zero and re-estimated the model. We did not include a decay term for the 2015 intervention as fewer time points were available between April 2015 and the end of our data series (June 2016). We used a linear underlying trend to fit the dispensing rate for standard strength PPIs and a square root of linear trend to represent the underlying trend in the dispensing rate for low strength PPIs.

We used the statistical package *mgcv* to perform seasonal adjustment of the data series [26] and estimated the intervention models using generalised non-linear least squares with the package *nlme* [23]. We performed all analyses in R v3.3.3 [27] and used a p-value of less than 0.05 to indicate statistical significance

## Results

We found that the 2009 NPS MedicineWise program was associated with a statistically significant reduction in the dispensing rate of standard strength PPIs ( $p < 0.0001$ ; Figure 1) and a significant increase in the rate of low strength PPI dispensing ( $p < 0.0001$ ; Figure 2). The 2015 NPS MedicineWise program was associated with a statistically significant reduction in the dispensing rate of standard strength PPIs ( $p < 0.0001$ ) but no change in the rate of low strength PPI dispensing (Table 4).

Compared to the expected rate of standard strength PPI dispensing without the interventions, we observed a 6.7% reduction in the rate of standard strength PPI dispensing from April 2009 until March 2015, with a total 8.6% reduction by June 2016 (Figure 1). The estimated reduction in dispensing of standard strength PPIs was 5.5/1,000 GP consultations per month following the 2009 program, and 14.9/1,000 GP consultations per month following the 2015 program. We did not observe evidence of a decay effect associated with the 2009 intervention (Table 4).

Compared to the expected rate of low strength PPI dispensing without the interventions, we observed a 5.6% increase in the dispensing rate by March 2015 (Figure 2). By June 2016, the overall increase in the dispensing rate of low strength PPIs was 5.0%. The estimated increase in the dispensing rate of low strength PPIs was 1.5/1,000 GP consultations per month following the 2009 program. We observed a slight, but non-significant increase in the rate of low strength PPI dispensing following the 2015 intervention (Table 4).

Table 4: Generalised linear and non-linear least square estimates of high and low strength PPIs monthly time series data

Variables in the Model	High Strength PPIs			Low Strength PPIs		
	Coefficient	95% CI	<i>p</i> -Value	Coefficient	95% CI	<i>p</i> -Value
Intercept	70.077	(69.09, 70.06)	<0.0001	13.546	(12.98, 14.17)	<0.0001

## Discussion

Our study demonstrated significant changes in the rates of PPI dispensing, as a surrogate measure of GP prescribing, following two targeted interventions, using national, whole-of-population dispensing data. We found that rates of standard strength PPI dispensing declined following the interventions, while dispensing rates for low strength PPIs increased after the 2009 intervention but not the 2015 intervention. These findings suggest that the NPS MedicineWise programs were effective in improving quality PPI prescribing by GPs in Australia.

Our results are consistent with recent studies of Australian veterans, which found that interventions conducted in 2004, 2006 and 2009 by NPS MedicineWise and by the Veterans' MATES program in 2006 and 2012 resulted in a 20.9% relative decrease in overall PPI dispensing and a 42.2% relative increase in low strength PPI dispensing 12 months after the final intervention in the veteran population [28]. Medicines dispensed to Australian veterans are subsidised through the Repatriation Pharmaceutical Benefits Scheme (RPBS), a funding body distinct from the PBS. Our data did not include RPBS dispensing records and our findings suggest that GPs may have applied new knowledge resulting from these programs in treating both their veteran and other community patients.

We estimated that the 2015 NPS MedicineWise program was associated with a 3.0% decrease in the standard strength PPI dispensing rate in the first 15 months following the intervention. This was greater than the 1.6% decrease during the 15 months after the 2009 intervention and the larger drop may be related to the Choosing Wisely Australia PPI campaign launched during the same month as the NPS MedicineWise 2015 intervention. The Choosing Wisely campaign was aimed at beginning a conversation between GPs and patients around the long-term use of PPIs; with Choosing Wisely members recommending regular attempts at lower strength prescribing or cessation of PPI therapy in patients with uncomplicated disease [17]. Although the impacts of the Choosing Wisely campaign and NPS MedicineWise program could not be separated, it is possible that each reinforced the messages of the other, resulting in a further reduction in the observed use of standard strength PPIs.

Other studies have shown the impact of educational programs on GP prescribing, including a study conducted by May et al. Doctors participating in an educational visiting program in Adelaide that focused on better use of prescribed non-steroidal anti-inflammatory drugs (NSAID) reduced their use of NSAIDs by 9% and 28% for two different measures compared to a comparison group [29]. Other studies have found positive impacts of educational programs on GP behavior, including programs on the treatment and management of incontinence, health behaviours of elderly people and adolescent health care [30-32].

Our study highlights the benefits of engaging with practitioners to improve the quality use of medicines. The goal of Choosing Wisely is to start discussions between physicians and patients around specific therapeutic practices. NPS MedicineWise actively engages general practitioners and consumers in educational activities aimed to improve the quality use of medicines through behaviour change [33]. There are potential opportunities for additional quality-use-of-medicines interventions, as well as on-going PPI education.

## **Strengths and limitations**

Our study evaluated changes to PPIs prescribed by GPs and dispensed to concessional patients over time. The cost of all PPI medicines subsidised by the PBS is above the concessional co-payment threshold and, therefore, we have a complete ascertainment of PPI dispensing for these concessional patients. The DHS began collecting dispensing data for medicines where cost was below the co-payment threshold for general non-concessional patients from April 2012 and based on dispensing data from that time it has been estimated that approximately 70% of PPIs prescribed by GPs were dispensed to

concessional patients. Nearly 88 per cent of prescription medicines dispensed under the PBS are for concessional patients. Concessional patients include low-income earners, welfare recipients, and Health Care Card holders and are higher users of health services due to their generally poorer health status. However, we expect the intervention impacts we observed in concessional beneficiaries would be similar among general beneficiaries as we do not expect the treatment of GORD with PPIs to differ between the two subsidy groups.

Proton pump inhibitors that are available from pharmacies without a prescription include rabeprazole, pantoprazole, esomeprazole and omeprazole. Standard strength esomeprazole received approval for over-the-counter (OTC) marketing in Australia in February 2016, and some of the reduction in standard strength PPI dispensing we observed following the April 2015 intervention could have been due to patients switching from prescription to OTC access for this medicine. However, the OTC formulation contained just a 7-day supply and the cost was above that of the concessional beneficiary co-payment in 2016 (\$6.20). We believe it is unlikely that many concessional beneficiaries would have switched to an OTC formulation. Concessional patients have limited funds available so it is unlikely they will pay for medicines that they can get at a cheaper price or for free if prescribed by their doctor under the PBS. The PBS has a safety net which resets each year on 1 January. In 2019, the PBS Safety Net threshold was \$390 for concessional card holders. Before meeting the threshold each medicine costs concessional patients \$6.50 and once they reach the threshold all PBS medicines are free of charge. This is an incentive for patients to pay the concessional rates for PBS medicines rather than buying those available over the counter from a pharmacist as not only are the medicines cheaper but the cost contributes to the patient reaching the Safety Net threshold. Non-concessional patients also have a safety net but due to the low cost of PPIs they do not have the cost covered under the PBS and are more likely to purchase PPIs over the counter than concessional patients.

Given the timing of the intervention programs, and that we did not identify any other potential confounding events following the 2009 and the 2015 programs that might explain the changes we observed, we believe that the change in the rate of PPI dispensing is attributable to the NPS MedicineWise programs and the Choosing Wisely RACGP recommendation although this study is observational and causality cannot be confirmed.

PBS data are maintained for the purpose of providing reimbursement to patients and pharmacies, and clinical information such as diagnoses, and treatment indications are not captured. Although the programs we evaluated were aimed at improving the quality use of PPIs, we are unable to assess the appropriateness of prescribing using these data. Similarly, our prescriber-level PBS data do not allow us to evaluate the rates at which individual patients switched between PPI treatment strengths or ceased PPI therapy.

The strengths of our study is the use of a longitudinal and complete dataset comprised of dispensing records for PPI medicines prescribed to concessional patients by every general practitioner in Australia

from 2006 to June 2016. These data allowed for robust estimates of trends over time in the exact population targeted by the interventions.

## Conclusions

The NPS MedicineWise programs were effective in changing the prescribing of PPI medicines by Australian GPs. These programs were complemented by a Choosing Wisely recommendation produced by RACGP which may have resulted in more efficacious interventions aimed at improving quality prescribing. Regular educational programs targeting the prescribing of PPIs may ensure that quality prescribing practices are continued.

## Abbreviations

DDDs – defined daily doses

GP – general practitioner

MBS – Medicare Benefits Schedule

OTC – over-the-counter

PBS – Pharmaceutical Benefits Scheme

PPI – proton pump inhibitors

RACGP – Royal Australian College of General Practitioners

## Declarations

### Acknowledgement

This research was funded by the Australian Government Department of Health through NPS MedicineWise. We acknowledge all staff at NPS MedicineWise who contributed and continue to contribute to the PPI programs. We acknowledge the Australian Government Department of Human Services for provision of the data used in this study.

**Ethics approval and consent to participate:** All data is deidentified and there was no further requirement for ethics approval.

### Consent for publication:

NPS MedicineWise and the Department of Human Services approved this manuscript before submission.

### Availability of data and material:

PBS and MBS data is available online – see the Australian Department of Health -
