Abstract

Background: Natural astaxanthin (ASTA) has strong antioxidant properties and has been widely used as a health product to improve human health. However, the effects of ASTA on the reproductive performance of aging roosters have been poorly studied. We aimed to investigate the effects of dietary ASTA on semen quality and antioxidant capacity in aging roosters and to explore the potential mechanism of semen quality change via anti-oxidation defense system.

Methods: In the present study, 96 53-week-old Jinghong No. 1 layer breeder roosters were fed a corn-soybean meal basal diet containing ASTA at 0, 25, 50, or 100 mg/kg for 6 weeks.

Results: Semen quality in the ASTA groups remarkably improved as compared to those in the control group and antioxidant activities, the abilities to scavenge hydroxyl radicals and superoxide anions increased gradually with ASTA addition ($P < 0.05$). In addition, the mRNA levels of antioxidant enzymes, the mRNA and protein levels of the mitogen-activated protein kinase (MAPK), nuclear factor-erythroid 2-related factor 2 (Nrf2) were markedly increased in the 50-100 mg/kg ASTA group ($P < 0.05$).

Conclusions: Collectively, these results demonstrate that dietary ASTA may improve semen quality by increasing antioxidant enzyme activities, and the ability to scavenge hydroxyl radicals, which may be related to up-regulation of the MAPK/Nrf2 pathway.

Introduction

In poultry production, assisted reproductive technology such as artificial insemination is widely used. A single male is responsible for fertilizing dozens of female birds[1]. Therefore, the reproductive performance of roosters is a key factor in production. However, the sperm quality of roosters decreases gradually at approximately 50–55 weeks[2]. Several important reproductive traits change in aging roosters, including decreases in the sperm concentration, motility, testosterone level, and antioxidant capacity[3; 4]. Male fertility is one of the most important factors in determining hatchability. Therefore, it is necessary to find a way to alleviate the influence of age on the reproductive characteristics of breeding roosters. Recently, studies have shown that dietary supplementation with natural anti-oxidative compounds such as dietary linseed oil[5], lycopene[6] and curcumin[7] can alleviate the negative effects of age on roosters.

Astaxanthin (3,3-dihydroxy-β, β-carotene-4,4-dione) is a xanthophyll carotenoid, that is mainly divided into two forms: natural astaxanthin (ASTA) and synthetic astaxanthin. ASTA can be extracted from algae[8], yeast[9], fish, krill, and some microorganisms[10]. The microalgae Haematococcus pluvialis (a green microalga) is one of the major sources of ASTA, and can be extract a large amount of ASTA under stress conditions[12; 11]. Although synthetic astaxanthin has the same chemical formula as ASTA, the ability to scavenge singlet oxygen and free radical of ASTA is over 50 times and 20 times that of synthetic astaxanthin, respectively [13]. Meanwhile, the European Commission considers ASTA as a food dye[14]. Currently, ASTA has received much attention for its various beneficial characteristics, including its anti-oxidant[15], anti-inflammatory[16] and anti-apoptotic properties[17]. However, there is little information on whether ASTA can improve the male reproductive performance.

The mitogen-activated protein kinase (MAPK) pathway, a family of serine/threonine protein kinases, is widely conserved in eukaryotes and is involved in antioxidant enzyme expression by modulating the Nrf2/ARE axis[18; 19]. Nuclear factor-erythroid 2-related factor 2 (Nrf2) is an important regulator of antioxidant responsive element (ARE)-activated gene expression. Nrf2 can repair and degrade of damaged macromolecules caused by oxidative stress by upregulating the expression of antioxidant enzyme genes[20]. Studies have shown that the MAPK/Nrf2 pathway improves the antioxidant capacity of eggs by upregulating the mRNA expression of P38MAPK, Nrf2, and HO-1[21]. Moreover, the Nrf2/ARE axis alleviates meat lipid peroxidation by regulating the expression of antioxidant enzymes and phase II enzymes in order to achieve long-term meat storage[22]. However, the potential effect of ASTA on sperm quality, antioxidant capacity, and the MAPK/Nrf2 antioxidant pathway in aging layer roosters was not clear.

Therefore, in the current study, we hypothesized that ASTA can improve semen quality by enhancing antioxidant capacity and activating the MAPK/Nrf2 pathway in aging roosters.
**Materials And Methods**

**Animal care and use**

All experimental protocols were approved by the Animal Care and Use Committee of the Beijing University of Agriculture.

**Experimental design**

In the present study, a total of ninety-six 53-week old Jinghong No.1 layer breeder roosters with a similar weight and genetic background were supplied by Beijing Huadu Group Co., Ltd. (Beijing, China), and the birds were randomly distributed in four treatments, following a completely randomized design. Each treatment had six replicates, and there were four birds per replicate with one bird per cage (70 cm × 60 cm × 75 cm). All birds were fed a basal diet for 1 week and then assigned to a corn-soybean meal-based diet containing 0, 25, 50, and 100 mg/kg ASTA for 6 weeks. *Haematococcus pluvialis* was purchased from Jingzhou Natural Astaxanthin Inc. (Jingzhou, China), and the ASTA content was 1.54%. The composition and nutrient levels of the corn–soybean meal-based diet are shown in Table 1. During the experimental period, the birds had 16-h light cycles and were allowed ad libitum access to water and the treatment diets.

¹The premix provided the following per kilogram of the diet: Cu 10 mg, Fe 80 mg, Mn 100 mg, Zn 80 mg, VA 20,000 IU, VD 3,000 IU, VE 30 IU, VK 2 mg, VB1 2 mg, VB2 10 mg, VB6 6 mg, VB12 0.012 mg, folic acid 1.2 mg, D-pantothenic acid 12 mg, nicotinic acid 40 mg, biotin 0.2 mg, and Se 0.3 mg.

**Semen collection and analysis**

Birds were trained for semen collection every 2 weeks. Semen samples were randomly collected from each bird in each replicate once every two weeks using the abdominal massage method. Next, semen volume was measured with a graduated collecting tube. Semen samples were diluted in a pre-warmed (37 °C) saline solution (0.9%, 1:49), after which samples were assessed for seminal characteristics using CASA system (WLJX-9000 Welli Color Sperm Analysis System; Welli New Century Science & Tech Dev., Beijing, China), including semen concentration and sperm motility parameters such as sperm motility (%), average path velocity (VAP, µm/s), straight linear velocity (VSL, µm/s), curvilinear velocity (VCL, µm/s), amplitude of lateral head displacement (ALH, µm), straightness (STR, %), linearity (LIN, %), wobble of the curvilinear trajectory (WOB, %) and beat cross frequency (BCF, Hz).

Sperm viability was evaluated using the eosin-nigrosin stain method. Briefly, a 5 µL sperm sample was mixed with 25 µL of stain on a pre-warmed slide before the test. Then, the stain was spread with another slide to make a sperm suspension smear. An Olympus BX51 microscope (Olympus Corporation, Tokyo, Japan) was used at a final magnification of 400 to analyze the sperm...
viability. For each sperm sample, five microscopic fields were observed subjectively, and 200 sperms were counted to evaluate viability. Sperm with unstained heads of spermatozoa were considered viable, while sperm displaying partial or complete purple staining were considered nonviable.

**Antioxidant enzymes and oxygen free radicals analysis**

After analyzing the semen quality, the semen sample was centrifuged at 4000 × g for 10 min at 4 °C, and then the seminal plasma was separated and stored at -20 °C. At the end of the 6-week feeding trial, one bird from each replicate was randomly selected and sacrificed by cervical dislocation. Immediately after euthanasia, blood samples were collected from the left jugular vein of one bird per replicate. Plasma was separated by centrifugation at 3000 × g for 10 min and stored at -20 °C until analysis. The testis, liver, and kidney were removed immediately and quickly frozen at -80 °C for later analysis. These samples were used to analyze the activities of antioxidant enzymes and the ability to scavenge oxygen free radicals. Briefly, antioxidant capacity included the glutathione peroxidase (GSH-Px), superoxide dismutase (SOD), catalase (CAT), and total antioxidant capacity (T-AOC), while oxygen free radical scavenging abilities included hydroxyl radical scavenging ability and superoxide anion scavenging ability. Meanwhile, malondialdehyde (MDA), as the product of lipid metabolism, was analyzed using a spectrophotometric method. These assays were performed using a commercial kit (Nanjing Jiancheng Bio-Engineering Institute, Nanjing, China). The method and principle used to determine the antioxidant indicators with these kits were previously described elsewhere [23].

**Quantitative PCR Analysis**

The mRNA expression levels of p38, extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase 1 (JNK1), c-Jun N-terminal kinase 2 (JNK2), c-Jun N-terminal kinase 3 (JNK3), Nrf2, Cu-Zn superoxide dismutase (SOD1), Mn superoxide dismutase (SOD2), CAT, glutathione peroxidase 1 (GPX1), and peroxidase 4 (GPX4) were determined via real-time quantitative PCR (RT-qPCR) with β-actin (ACTB) as an internal control in the testis tissues. Total RNA was isolated from 0.1 g of the testis sample using TRizol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's protocol. Then, 1% agarose gel stained with ethidium bromide was used to confirm the 18S and 28S bands. Finally, the total RNA concentration was measured using a spectrophotometer at 260 nm. Total RNA was reverse transcribed into cDNA using a Thermo Fisher First cDNA Synthesis Kit (#K1621; Thermo Fisher Scientific, Waltham, MA, USA). A Step One Plus Real-time PCR system (Applied Biosystems, Foster City, CA, USA) was used for the quantitative PCR analyses. The primers for the selected genes are listed in Table 2. After initial denaturation at 95 °C for 10 min, 40 cycles of amplification were performed (95 °C for 10 s and 58 °C for 30 s), generating melt curves to verify amplification specificity. The relative gene expression levels were calculated using the $2^{-\Delta\Delta C_{i}}$ method[24], with ACTB as the reference gene.

Western blotting analysis

The protein expression of Nrf2, p38, p-p38, ERK, p-ERK, JNK, and p-JNK was evaluated by western blotting in the testis tissues, and the antibodies are shown in Table 3. Total proteins were extracted from testis tissues using RIPA Buffer (W1001; SinoGene, Beijing, China) according to the manufacturer's instructions. The protein concentration of the extracts was determined using the Bradford method (W1014; SinoGene). Samples containing 30 µg of protein and protein markers (SM26616; Thermo Fisher Scientific) were separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE; 4% stacking gel, 12% separating gel) at 120 V for 2 h. Proteins were transferred to polyvinylidene difluoride (PVDF) membranes using a Bio-Rad mini transfer system (Bio-Rad Laboratories, Hercules, CA, USA). The membranes were blocked with Fast Protein-free Block Buffer (#W1028; SinoGene) for 5 min and then incubated with primary antibody (1:1000 dilution) overnight at 4 °C. After rinsing four
times with TBST for 10 min per rinse, HRP-conjugated secondary antibody (SA00001-2, ptg) was applied to the membranes at a dilution of 1:3000 for 1 h. Then, after rinsing three times with Tris-buffered saline with 0.1% Tween® 20 Detergent (TBST) for 10 min per rinse, immunological signals were detected using a chemiluminescent (ECL) kit (29050; Engreen) and exposed to X-ray films in the dark. Protein bands were quantified by densitometric analysis using Image J analysis software (National Institutes of Health, Bethesda, MD, USA).

Statistical analysis

Statistical analysis was performed using SPSS 22.0 (IBM Corp., Armonk, NY, USA). Data related to the effect of dietary ASTA levels on semen quality, antioxidant capacity, gene and protein expression were analyzed by one-way analysis of variance with orthogonal linear and quadratic contrasts. Duncan's multiple comparison test was used to examine statistical differences among the treatments. Statistical significance was defined as \( P < 0.05 \).

Results And Discussion

Semen quality

Semen quality is considered to be a crucial factor in roosters' fertility because the fertility rate is positively correlated with sperm motility, sperm concentration, and sperm motility parameters in roosters[25]. Few reports have described the effects of ASTA on semen quality in aging roosters. We evaluated the effects of dietary ASTA on semen quality in aging roosters (Table 4). Briefly, there were no differences in semen quality between the control group and the ASTA groups at week 0. The semen volume was significantly higher in the 25 mg/kg ASTA group than that in the other groups at week 6 \( (P < 0.05) \). Meanwhile, with an increase in dietary ASTA, sperm viability and sperm concentration significantly increased compared to those in the control group \( (P < 0.05) \). In particular, the sperm concentration was linearly and quadratically affected \( (P < 0.05) \) by the dietary ASTA levels. In addition, the sperm motility parameters of aging layer roosters in the 50 mg/kg ASTA group were significantly linearly increased relative to those in the control group \( (P < 0.05) \). Moreover, sperm motility increased from 64.395–76.234% in the 0–100 mg/kg ASTA-treated group \( (P < 0.05) \). It has been previously demonstrated that sperm viability, total motility, and sperm kinematic parameters increase after ASTA treatment in mice[26]. A recent study also showed similar results: ASTA can improve post-thawed rooster sperm motility and kinetic parameters, including total motility, progressive motility, VAP, VSL, and LIN. However, there was no significant difference in LIN, STR, ALH, and BCF in the ASTA treatment groups compared to those in the control[27]. Interestingly, the opposite result was observed in the current study that the motility parameters including STR, LIN, WOB, VSL, VAP, BCF, and ALH in the ASTA groups were significantly higher than those in the control group \( (P < 0.05) \). The discrepant results may be partly related to the level of ASTA addition, the duration of supplementation, and the test subjects. Taken together, these findings indicated that dietary ASTA supplementation significantly increased the semen quality during the test period (0–6 weeks). However, the possible mechanisms by which dietary ASTA affects semen quality are not well understood, but may be related to antioxidant defense system.

<sup>a−d</sup> Means within a row with no common superscripts differ significantly (P<0.05). Data represent the mean of six replicates. Abbreviations: SEM, standard error of the mean; ANOVA, analysis of variance; VAP, average path velocity; VSL, straight linear velocity; VCL, curvilinear velocity; ALH, amplitude of lateral head displacement; STR, straightness; LIN, linearity; WOB, wobble of the curvilinear trajectory; BCF, beat cross frequency.

Antioxidant enzyme activity and free radical scavenging ability

In aging roosters, a decreased in the antioxidant defense system, makes rooster spermatozoa vulnerable to lipid peroxidation[28]. Other studies have reported that senescence occurs due to the damage caused by free radicals and reactive oxygen species (ROS) to DNA, lipids, and proteins[29; 30]. Sophisticated enzymatic (SOD, CAT and GSH-Px) and non-enzymatic (vitamins A, C, E, and carotenoids) antioxidants constitute an antioxidant defense system that can regulate overall ROS levels to maintain physiological homeostasis[31]. ASTA, as a natural carotenoid antioxidant, can be transferred to the right place in the tissues and exert antioxidant effects at an appropriate concentration[32]. Previous studies have demonstrated that ASTA has a higher antioxidant activity relative to α-carotene, lycopene, lutein, and β-carotene[33], and the capacity of scavenging singlet oxygen is about 550 times more than that of vitamin E[34]. Thus, in this study, the effects of dietary ASTA addition on antioxidant enzyme activity and free radical scavenging ability in the plasma, seminal plasma, testes, liver, and kidney of aging layer breeder roosters are shown in Figures 1 to 5. Briefly, the 25 mg/kg ASTA level linearly and quadratically increased the GSH-Px activity in the plasma, testis, and liver of aging layer roosters compared with that in the control group (P<0.05). The activities of SOD and CAT also increased gradually with increasing dietary ASTA supplementation from 50 to 100 mg/kg (P<0.05). Furthermore, MDA
Gene expression of SOD1, SOD2, CAT, GPX1, and GPX4

The activity of an antioxidant enzyme is closely related to its gene expression[42]. The mRNA levels of SOD1, SOD2, CAT, GPX1, and GPX4 were determined to evaluate the effects of ASTA on the gene expression of antioxidant enzymes in aging rooster testis tissues (Figure 6). In the present study, the SOD1 and SOD2 mRNA levels in the 50 mg/kg ASTA groups were higher than those in the other groups (P < 0.05). SOD1 is mainly soluble in the cytoplasm and SOD2 is mitochondrial, and ASTA has both lipophilic and hydrophilic properties, which can directly produce effects in or outside the cell membrane[43]. This may be the reason why the gene expression of SOD1 and SOD2 was improved by adding dietary ASTA. Additionally, in the dietary ASTA supplementation group, the GPX1 and GPX4 mRNA levels were significantly increased relative to those in the control group (P < 0.05). However, there were no differences in the GPX1 mRNA levels among the 50 and 100 mg/kg ASTA-treated groups. Furthermore, an increase in dietary ASTA supplementation from 0 to 100 mg/kg linearly increased the mRNA expression of CAT (P < 0.05). Similarly, in a previous study, dietary ASTA increased the oxidative damage repair potential of mice and upregulated the mRNA levels of GPX1, SOD1, SOD2, and CAT in the liver and kidney[44]. Therefore, it would be interesting to further study the mechanism of how dietary ASTA affects semen quality in aging roosters by improving the antioxidant defense system.

Gene and protein expression in the MAPK/Nrf2 pathway

Nrf2 plays an important role in the antioxidant response, and it has been reported that the MAPK kinase pathway regulates the Nrf2 action. When the nuclear transcription factor Nrf2 is phosphorylated and activated by MAPKs (such as ERK and P38), it can be translocated to the nucleus, leading to the upregulation of antioxidant enzyme expression[22]. Therefore, in order to clarify whether ASTA could activate this pathway, the gene and protein expression in the MAPK/Nrf2 pathway in testis tissues were measured in the four groups, and the results are presented in Figures 7 and 8. In this study, significant differences in the mRNA levels of Nrf2, ERK, P38, and JNK were observed among all of the ASTA-added groups in the testis (Figure 7). Briefly, when the concentration of dietary ASTA reached 50 mg/kg, the mRNA levels of Nrf2, ERK, P38, and JNK2 were significantly higher than those in the control group (P < 0.05) and reached the maximum. A significant increase in JNK1 mRNA expression was observed in the 100 mg/kg ASTA group (P < 0.05). Moreover, an increase in dietary ASTA from 0 to 100 mg/kg linearly enhanced the mRNA expression of JNK3 (P < 0.05). This finding indicated that dietary ASTA increased the gene expression of Nrf2 and upregulated...
the expression of upstream signals (MAPKs). Western blot analysis revealed that dietary ASTA effectively elevated ($P < 0.05$) the ratio of the phosphorylated MAPKs (p38, ERK, and JNK) to total MAPKs (p38, ERK, and JNK) compared to that in the control (Figure 8). Briefly, the results showed that ASTA treatment remarkably upregulated the p-p38, p-ERK, and p-JNK expression in the testis ($P < 0.05$). In particular, the p-p38, p-JNK, and Nrf2 protein levels in the 25 mg/kg ASTA group were higher than those in the other groups. In addition, when the concentration of dietary ASTA reached 50 mg/kg, p-ERK protein levels were significantly higher than those in the control group ($P < 0.05$) and reached the maximum. However, Niu et al., 2018 [45] observed an opposite result in that dietary ASTA supplementation did not affect the p-38 and p-JNK levels but significantly increased the p-ERK levels. Differences in test subjects, and test conditions may explain these discrepant results.

**Relationships among the MAPK/Nrf2 pathway and antioxidant enzymes and semen quality**

Aging is a complex phenomenon that is associated with an irreversible and progressive decline in body function due to biochemical and morphological changes[46]. In the process of aging, there are obvious characteristics such as increase in oxidative stress, a decline in cell function, and defects in tissues and organs[47]. In aging male animals, morphological changes in the testis include a reduction in the volume and quantity of germ cells, which leads to a decrease in sperm quality and fertilization[48]. Therefore, in this study, we explored whether dietary ASTA can improve the semen quality of aging roosters by activating the MAPK/Nrf2 pathway to enhance the service life of aging roosters. The MAPK signaling pathway is involved in many cellular functions, such as inflammation, cell proliferation, cell differentiation, and cell death[18]. Meanwhile, the MAPK signaling pathway can regulate the expression of antioxidant enzymes in various cell types and adapt to various extracellular stresses through the Nrf2/ARE axis[49]. Nrf2 is a major factor that regulates antioxidant responses, and dissociates from Keap1 upon the oxidative response and translocates to the nucleus, wherein it is phosphorylated at serine 40 by the MAPK pathway, leading to the upregulation of the gene expression of antioxidant enzymes[50]. There is a high proportion of polyunsaturated fatty acids in the plasma membrane of bird sperm, and with an increase in age, the antioxidant capacity of sperm decreases. Once the plasma membrane of bird sperm is exposed to ROS, it is prone to lipid peroxidation [51]. Thus, the decrease in total antioxidant capacity of semen is considered to be one of the reasons for the decline of fertilization ability in aging roosters[52]. In the current study, our results revealed that dietary ASTA elevated the MAPK phosphorylation (p38, ERK, JNK), and the mRNA and protein expression of Nrf2 were remarkably enhanced by adding 50 mg/kg ASTA in the diets, which was in agreement with a previous study[53]. In addition, the *SOD1*, *SOD2*, *CAT*, *GPX1*, and *GPX4* mRNA levels were higher in the dietary ASTA group than those in the control group, which led to the enhancement of antioxidant capacity and semen quality in aging roosters. These results indicate that dietary ASTA can activate the MAPK/Nrf2 pathway, upregulate Nrf2 transcription and translation, and promote the expression of downstream antioxidant enzyme genes, enhancing the antioxidant capacity and improving the semen quality in aging roosters.

**Conclusions**

In summary, the results of this study confirmed our hypothesis that dietary ASTA supplementation improves the semen quality of aging roosters, as reflected by the upregulation of the antioxidant system (Fig. 9). Therefore, these findings suggest that dietary ASTA could attenuate age-related sub-fertility in aging layer breeder roosters. However, the possible mechanisms by which ASTA ameliorates sperm quality are not well understood. Therefore, it is necessary to evaluate the effect of dietary ASTA on semen quality by the MAPK/Nrf2 signaling pathway in vitro.

**Abbreviations**

ACTB, β-actin; ALH, amplitude of lateral head displacement; ARE, antioxidant responsive element; ASTA, natural astaxanthin; BCF, beat cross frequency; CAT, catalase; GPX1, glutathione peroxidase 1; GPX4, peroxidase 4; GSH-Px, glutathione peroxidase; ERK, extracellular signal-regulated kinase; JNK1, c-Jun N-terminal kinase 1; JNK2, c-Jun N-terminal kinase 2; JNK3, c-Jun N-terminal kinase 3; LIN, linearity; MAPK, mitogen-activated protein kinase; MDA, malondialdehyde; Nrf2, Nuclear factor-erythroid 2-related factor 2; SOD, superoxide dismutase; SOD1, Cu-Zn superoxide dismutase; SOD2, Mn superoxide dismutase; STR, straightness; T-AOC, total antioxidant capacity; VAP, average path velocity; VCL, curvilinear velocity; VSL, straight linear velocity; WOB, wobble of the curvilinear trajectory.
