Abstract

Background: Ethiopia is the second populous countries in Africa where millions of children are affected by malnutrition. Several original works are available online about child malnutrition in Ethiopia. The aim of this study was to summarize the existing epidemiological data on undernutrition and possible determinants among school children in Ethiopia.

Methods: We conducted a systematic review using open access articles which report prevalence of stunting and wasting/thinness from PubMed Central, Scopus and Science direct. From 358 articles accessed online, 39 of them were eligible for this meta-analysis. The heterogeneities among studies were evaluated using I² test and the pooled prevalence was calculated using a random effect model.

Results: A total of 24,716 school children were included in 39 eligible articles for this meta-analysis. The pooled prevalence of stunting and wasting/thinness among school children in Ethiopia were 23.1% (95% CI: 19.0 - 27.0%) and 22% (95% CI: 17% - 26%), respectively. The risk of stunting was increased among the student with meal frequency ≤3 times a day (OR= 3.02, 95% CI: 1.90 - 4.14), age > 10 years (OR= 2.16, 95% CI: 1.47 - 2.85) and family size ≥5 (OR= 1.88, 95% CI: 1.40 - 2.35). Similarly, the risk of wasting/thinness was increased with male sex (OR= 2.06, 95% CI: 1.54 - 2.58), low family income (OR= 2.16, 95% CI: 1.30 - 3.01) and age > 10 years (OR= 1.78, 95% CI: 0.74 - 2.82). High heterogeneity about the prevalence of stunting and wasting/thinness was observed among studies included in this meta-analysis (I² > 98.6).

Conclusions: This study showed that stunting and wasting/thinness are common nutritional problems in school children in Ethiopia. Large family size, male sex and age above 10 years were consistently associated with stunting and wasting/thinness in children. The finding of this study highlights the importance of new strategies to reduce undernutrition in Ethiopia.

Keywords: stunting, wasting, thinness, undernutrition, systematic review, meta-analysis

Introduction

Undernutrition is the inability of obtaining right amount of nutrients that fulfill the body demand for optimum function. It is one of the major causes of child morbidity and mortality in developing countries. Undernutrition is classified into stunting, underweight, wasting/thinness and deficiency of vitamins and minerals [1]. Stunting is a chronic form of undernutrition which reflects previous failure of optimum growth while wasting/thinness is an acute form of malnutrition that indicates recent food shortage [2]. Underweight indicates a combination of acute and chronic malnutrition at a time [1].

According to WHO, stunting and wasting affect 150 million and 52 million children, respectively [3]. The problem of undernutrition is severe in Africa and Asia, where more than 90% of stunted and underweight preschool children are living in the two regions [4, 5]. The global prevalence of stunting and wasting among preschool children were 36% and 8.5%, respectively in Africa in 2011 [4]. Similarly, stunting and
thinness affecting 20 - 30% and 35% school children in Africa, respectively [6]. Despite the millennium development goal targeting reduction of undernutrition, the problem is still high in sub-Saharan African countries. As stated in the 2015 MDG report, 23% of children in sub-Saharan Africa are undernourished [7]. The prevalence of undernutrition above 20% is considered as a public health importance [8]. Therefore, undernutrition is still one of the major challenges for children living in African countries. Chronic undernutrition further leads to serious problem in child health, physical growth and school performance.

Child malnutrition is one of the serious problems among children in Ethiopia, where more than 55% of the population are below the age of 19 years. According to the 2007 population census, school aged children (7–18 years of age) accounts for 34.3% of the total populations of Ethiopia [9]. In line with this, the 2008 national nutritional survey indicated that 22.3% and 23.1% of school children were stunted and thinned, respectively [10]. The number of published articles on the prevalence of undernutrition and possible risk factors in the country is significantly increased since the 2008 national survey. However, there is a huge discrepancy about the prevalence of undernutrition and their potential risk factors among published studies. To my best knowledge, there were no summarized data on the prevalence undernutrition and potential determinants among school children in Ethiopia. Therefore, this systematic review and meta-analysis aimed to summarize online available published studies on the prevalence of undernutrition and possible determinant factors in Ethiopia.

**Methods**

**Children age category in Ethiopia**

This study is conducted in Ethiopia, which is the second populous country in Africa with an estimated population of 105 million and an area coverage of 1,104,300 km$^2$. Out of the total population, 55.6% of them are children below the age of 19 years. Children are supposed to enroll in primary school at the age of 7 years and spent an average of 12 years at school in Ethiopia. The first cycle starts from grade 1 to 4 (7–10 years), second cycle from grade 5 to 10 (11–16 years) and preparatory school in grade 11 & 12 (17–18 years). Thus, school aged children in Ethiopia is ranges from 7 to 18 years of age. Most nutritional studies in Ethiopia were conducted at primary and secondary school children. Therefore, all studies included in this systematic review and meta-analysis was conducted on primary and secondary school children.

**Anthropometric indicators**

Anthropometric indicators namely stunting, underweight, wasting or thinness were used based on NCHS/WHO definition [11]. The Z-score value below minus two standard deviation (−2 SD) from NCHS/WHO reference population was considered to determine undernutrition. Children were labeled as stunted (height-for age < −2 SD), underweight (weight-for-age < −2 SD) and wasted or thinned (weight-
for-height or body mass index (BMI)-for-age < −2 SD) [2, 11]. Weight-for-height is applicable for children below the age of 10 years to determine wasting while BMI-for-age is used for children from 5–19 years of age to assess children thinness [11]. Therefore, all articles selected and included in this meta-analysis were based on NCHS/WHO growth reference parameters.

Search strategies

Relevant literatures were systematically searched from three online databases (PubMed Central, Scopus and Science Direct) using the following key words: “Ethiopia”, “undernurition”, “malnutrition”, “acute malnutrition”, “chronic malnutrition”, “stunting”, “wasting”, and “thinness”. Searching of relevant articles used for this meta-analysis was conducted from December 2018 to January 2019. The systematic review and selection of relevant literatures were conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines [12] (Additional file 1: Table S1).

Selection, inclusion and exclusion criteria

Original articles reporting the prevalence of undernutrition (stunting and wasting/thinness) and possible predictors in school children in Ethiopia were selected for this study. Articles containing the prevalence of stunting, wasting/thinness and associated risk factors along with age range of students, total study population and study area were included for this systematic review and meta-analysis. All articles included in this meta-analysis were written in English and published between 2009 and 2018. Nutritional studies conducted on preschool children, community based study, specific groups (only female or male students), patients, reports form review paper or conference abstract were excluded from this meta-analysis.

Methods of data extraction

Literatures were extracted from online databases using data extraction protocol developed by the author. The data extraction protocol consists of sample size, method of participant selection, age group, study design, study regions, year of publication, prevalence of stunting and wasting/thinness and risk factors of undernutrition. The summarized information was used to determine the overall prevalence as well as major determinants of undernutrition among school children in Ethiopia.

Quality assessment

The quality of individual studies included in this meta-analysis was assessed using STROBE (Strengthening the Reporting of Observational studies in Epidemiology) checklist [13]. The checklist is used to assess internal validity (measurement biased) and external validity (selection biased) of studies.
included in this-meta-analysis. Among the 22 STROBE items, we select 8 quality assessment parameters namely sample size, sampling methodology, response rate, statistical analysis, ethical consideration, outcome measure, confounding and study limitation (Additional file 2: Table S2). Studies were assigned either 1 (if the criterion was met) or 0 (if the criterion was not met). The overall quality score was determined by adding the assigned number for each parameter and classified as low quality ($\leq 3$), medium quality (4 - 6) or high quality ($\geq 7$) as described elsewhere [5].

**Statistical analysis**

The prevalence of undernutrition (stunting and wasting/thinness) was calculated by dividing the number of positive subjects by the total study participants. The heterogeneity among studies used for this meta-analysis was assessed using $I^2$ test [14]. Heterogeneity is defined as the degree of variability across studies. The heterogeneity of the studies were classified as low, moderate and high based on the $I^2$ value less than 25%, 25 - 50% and above 50%, respectively [15]. Considerable heterogeneity was observed among the studies included in the meta-analysis. Thus, a random-effect model at 95% CI was used for estimating of the overall effect. The meta-analysis was conducted using Stata software (version 14, STATA Corp College Station, TX), where $p < 0.05$ was considered as statistical significant.

**Results**

**Characteristics of the eligible studies**

A total of 358 studies about undernutrition in school children in Ethiopia were available in the selected online databases. Out of those articles, 141 articles were excluded based on duplication while 112 articles were excluded during title and abstract screening. The remaining 105 full text articles were assessed for their eligibility. Of those articles, 66 were excluded from the analysis based on specific exclusion criteria (Fig. 1). The remaining 39 articles were included for this systematic review and meta-analysis. The detailed characteristic of eligible articles included in this meta-analysis was presented in Table 1.

The 39 eligible original articles were obtained from 5 regions (Amhara, Oromia, Somali, South Nations and Nationalities Peoples (SNNP) and Tigray) and 1 city administration (Addis Ababa). These regions and city administration accounted for more than 95% of the total population of Ethiopia. A total of 24,716 school children were included in the 39 eligible articles [16-54]. Among these eligible articles, 26 contain data for both stunting and
wasting/thinness while 13 articles addressing either stunting or wasting/thinness. Therefore, 38 articles and 27 articles were used for the analysis of stunting and wasting/thinness, respectively. All studies included in this meta-analysis were conducted on school children with a minimum age of 4 years and the upper limit was not mentioned in few studies.

### Quality assessment

The overall quality assessment of each article included in this meta-analysis was moderate to high quality score; 7 studies (17.9%) with moderate quality score while 32 studies (82.1%) with high quality score (Additional file 3: Table S3).

### Prevalence of stunting among school children in Ethiopia

The pooled prevalence of stunting was 23.1% (95% CI, 19.0 - 27.0%) among school children in Ethiopia (Table 2 and Fig. 2). The highest pooled prevalence of stunting was 29.5% (95% CI, 27.6-32.5%), which was observed from Tigray region while the lowest prevalence of stunting was 12.9% (95% CI, 8.9% - 16.9%) obtained from Oromia region (Table 2). A single study was available from the Somali region that indicate low prevalence of stunting but not fair to compare with other regions based on a single finding.

### Prevalence of thinness/wasting among school children in Ethiopia

The pooled prevalence of thinness/wasting was 22% (95% CI, 17% - 26%) among school children in Ethiopia (Table 2 and Fig. 3). The overall prevalence of wasting/thinness was higher in Tigray region, 39.9% (95% CI, 32.1% - 47.8%), followed by Amhara region, 22.9% (95% CI, 21.8% - 24.1%) while lower pooled prevalence was obtained from Oromia region, 14.1% (95% CI, 12.8% -15.4%) (Table 2).

### Associated factors of stunting among school children in Ethiopia
We have reviewed and analyzed potential determinants of stunting among school children from 21 eligible articles in Ethiopia. Age and sex of the students, family size, meal frequency, mother education, rural residency and presence of parasitic infections were associated with stunting of school children in Ethiopia (Fig 4). The pooled results of 14 studies [19, 21, 24, 27, 28, 35, 36, 38, 39, 41, 45-47, 53] showed that students above ten years of age were 2.16 times more likely to be stunted than students below ten years of age (OR = 2.16, 95% CI: 1.47-2.85) (Fig. 4a). The pooled results of 5 studies [17, 19-21, 38] showed that students with meal frequency at most three times a day were 3.02 times more likely to be stunted as compared to students with meal frequency more than three times a day (OR = 3.02, 95% CI: 1.90 - 4.14) (Fig. 4b).

The pooled effect size of five studies [23, 28, 38, 39, 46] showed that students with larger family size 1.88 times more likely develop stunting than students with small family size (OR = 1.88, 95% CI: 1.40-2.35) (Fig. 4c). The pooled results of six studies [19, 20, 34, 39, 45, 53] revealed that male students were 1.74 times more stunted than female counterparts (OR =1.74, 95% CI: 1.36-2.12) (Fig.4d). The pooled effect size of seven studies [21, 28, 35, 36, 39, 49, 53] indicated that students from rural residency were 1.59 more likely stunted than students from urban areas (OR = 1.59, 95% CI: 0.82-2.36) (Fig. 4e). Similarly, the pooled results of five studies [17, 35, 41-43] indicated that students infected with parasite organism were 1.48 times more likely develop stunting than students without parasitic infection (OR = 1.48, 95% CI: 0.40 - 2.56) (Fig. 4f).

Associated factors of thinness/wasting among school children in Ethiopia

We have reviewed and analyzed potential determinants of thinness/wasting among school children in Ethiopia from 13 eligible articles. Sex of students, age of students, family size, presence of parasitic infections and family income were associated with thinness/wasting among school children in Ethiopia (Fig. 5). The pooled results of six studies [34, 47, 49, 50, 53, 54] revealed that male students were 2 times more likely to be thinned/wasted than
female counterparts (OR = 2.06, 95% CI: 1.54 - 2.58) (Fig.5a). Based on the pooled results of three studies [19, 38, 41], students living with a low family income were about 2 times more likely to be thinned/wasted than students living with better income family (OR = 2.16, 95% CI 1.30-3.01) (Fig. 5b)

The pooled results of five studies [24, 36, 47, 50, 53] revealed that students above 10 years of age were 1.78 times more likely to be thinned/wasted than students below ten years of age (OR = 1.78, 95% CI: 0.74 - 2.82) (Fig.5c). The pooled effect size of four studies [20, 24, 38, 41] showed that students with family size above five were 1.72 times more likely to be thinned/wasted as compared with students living with a lower family size (OR = 1.72, 95% CI: 0.98 - 2.47) (Fig. 5d).

**Discussion**

Child malnutrition is one of the major global problems that affect millions of children worldwide. The problem is severe in developing regions particularly in sub-Saharan Africa and South Asia where more than 20% of children are affected by undernutrition [55]. Epidemiological studies on undernutrition are essential to assess the prevalence of undernutrition, outcome of previous intervention programs as well as to design alternative strategies by policy makers. In line with this, several epidemiological data are available online on the prevalence of undernutrition and possible risk factors in Ethiopia. To the best of my knowledge, this is the first systematic review and meta-analysis on undernutrition and possible determinants among school children in Ethiopia.

The pooled prevalence of stunting and wasting/thinness observed in the present study is nearly similar to the result of 2008 national survey [10]. This indicates there is no observable change in the last ten years, despite coordinated efforts to reduce the burden of undernutrition in the country. The Ethiopian government and other stockholders are working on food supplementation through school feeding programs as of 2005 in selected schools. School feeding programs are known to bring positive impact on student’s school attendance, academic performance as well as physical growth [56]. However, there is no
apparent change observed on the prevalence of undernutrition in school children in the country. A lot of works need to be done in the country to reduce the burden of stunting and thinness in school children.

The overall prevalence of stunting among school children in the present study was similar to 22.3% reported in the 2008 national survey in Ethiopia [10], 22% from African countries average [6] and 21.7% among young adolescents in Africa [57]. However, the pooled prevalence of stunting in this study was lower than 35% reported in a meta-analysis from school children in Karnatake, India [58] and 60% from Bangladesh [59]. All these data showed that undernutrition is significantly high in Africa and South Asia. Despite the millennium development goal designed to reduce the prevalence of stunting, the problem is still remains high in sub-Saharan Africa and South Asia.

The pooled prevalence of thinness/wasting among school children in Ethiopia was similar to that of the 2008 national survey [10]. However, the present finding was low as compared with 36% reported from a meta-analysis in African [6] and 28% from India [58]. The high prevalence of thinness and wasting are linked with low family income, which is still a problem in many Ethiopians. Wasting and thinness are an acute form of malnutrition directly associated with family income, which determine the meal frequency as well as the diversity of diet. The government of Ethiopia needs to improve the living standard of the population particularly low income earners.

We reviewed and analyzed risk factors associated with stunting and wasting/thinness of school children addressed by selected articles for this meta-analysis. Identification of major risk factors of undernutrition is essential to design cost effective intervention strategies to improve the health and growth related problems in children. The risks of developing childhood stunting and wasting/thinness were consistently associated with male sex, age above 10 years and living with a larger family size (above five). The contribution of these risk factors to stunting and wasting/thinness were also reported in a meta-analysis from other African countries [5].
The risk of developing stunting was higher among children taking meal at most three times a day compared to their counterparts. It is clear that meal frequency is directly associated with family income. Children living in area where problems of food shortage or low family income, they have higher chance of being stunted and underweight [60]. The levels of family income dictate the provision of balanced diet as well as frequency of meal to their children. Long-term exposure for food shortage an early stage of child leads to chronic malnutrition namely stunting. The level of meal frequency at early childhood play vital role for their physical growth and development.

This study revealed that the risk of stunting and wasting/thinness was higher among male children compared with female counterparts. This result is in line with several studies in sub-Saharan Africa [5, 57, 61, 62]. This variation might be associated with differences in physical activity between male and female children in the region. In most sub-Saharan African countries male children help their parents through involvement in energy demanding on-farm and off-farm activities. In addition, males children are more physically active than their female counterpart particularly during childhood [63]. As a result, male children may lose their energy needed for normal growth and other physiological activities that may leads to stunting or thinness. The problem is more severe if this energy loss is accompanying with low meal frequency and minimum diet.

The risk of stunting and wasting/thinness was higher among student above 10 years of age compared with lower age groups, which is in line with a meta-analysis reported from Iran [60] and sub-Saharan Africa [5]. Higher risk of stunting was reported from boys than girls in many African countries include Tanzania [64], Burkina Faso [65] and Uganda [62]. In many African countries, older age children particularly males are involved in energy demanding on-farm activities. Low meal frequencies accompanied with several outdoor activities make male and older children vulnerable for undernutrition especially for stunting and thinness.

There was a remarkable difference in undernutrition between children living within small and larger family size. The odd of being stunted and wasted/thinned was higher in students
living with a larger family size than those living with a small family size. The contribution of large family size and low income to childhood undernutrition were reported from in Pakistan [66] and sub-Saharan Africa [5]. Children living within a large family size are exposed to nutritional related problems due to shortage adequate diet, poor living and health conditions. Ethiopia is one of the sub-Saharan African countries known in large family size, which predispose children to nutritional related problems.

The presence of parasitic infection and rural residency were increased the risk of stunting among school children in Ethiopia. Chronic parasitic infection particularly helminths are contributing for childhood undernutrition by competing for the available limited nutrients. Conversely, malnourished children are susceptible for parasitic infections, which further aggravate the level of undernutrition. The positive associations of soil transmitted, and undernutrition was reported elsewhere [67-69]. Children living in rural areas are easily exposed for parasitic infection due to high level of environmental sanitation and poor personal hygiene. Therefore, both rural residency and parasitic infections are contributing factors to nutritional related problems in school children in Ethiopia.

**Significance/contribution**

Exposures of undernutrition during childhood are affecting their health, physical growth, mental development, work capacity and quality of life during the entire lifespan of an individual. Therefore, assessments of nutritional status of school children are essential tools for policy makers to design appropriate intervention strategies. This study determines the pooled prevalence of undernutrition, major risk factors, and potential target regions for intervention in the country. Therefore, the result of this meta-analysis will help policy makers to evaluate the existing intervention strategies as well as to design alternative approaches to reduce undernutrition among school children in Ethiopia.

**Strength and limitations**

This study provides the pooled prevalence of stunting and wasting/thinness among school children in Ethiopia. The present study identifies variation of stunting and wasting/thinness
in school children among the different regional states in Ethiopia. In addition, this study identifies major risk factors associated with stunting and wasting/thinness in Ethiopia, which are important supplement for policy makers. Despite these strengths, the study has a number of limitations. First, this meta-analysis did not include underweight among school children due to lack of consistency among the parameters used in the selected articles for this review. Second, the numbers of articles used in this study were not uniformly distributed across regions in the country. Third, the present study did not show the level of variation of stunting and wasting/thinness between sexes.

**Conclusions**

This study revealed that the prevalence of stunting and wasting/thinness among school children is remaining high in Ethiopia. The existing nutritional intervention strategies did not bring significant change in nutritional status of school children in the country. Therefore, there is an urgent need of design alternative intervention strategies to reduce the level of undernutrition among children in Ethiopia. The present study identifies a number of risk factors associated with stunting and wasting/thinness of school children. The identified risk factors in this review can be potential targets to design new interventions strategies by policy makers in the country.
