# Abstract

**Background:** Vasculogenic mimicry (VM) plays an important role in human glioma progression and resistance to antiangiogenic therapy as a compensatory neovascularization mechanism in malignant tumors. Caveolin-1 (Cav-1) has been found to contribute to VM formation. However, it remains largely unknown whether Cav-1 expression correlates with VM in glioma. **Methods:** In this study, by performing immunohistochemical staining of Cav-1 and CD31/Periodic acid–Schiff co-staining, we found that Cav-1 expression and VM formation were positively correlated with each other and both are closely associated with glioma development and progression as evidenced by the presence of cystic tumor, the shortened survival time and advanced-stage glioma in glioma patients with Cav-1 overexpression/increased VM formation, suggesting Cav-1 as a prognostic indicator in glioma. **Results:** Gain- and loss-of-function analyses showed that Cav-1 promoted U251 glioma cell proliferation and VM formation in a Matrigel-based 3D culture model. Mechanistically, overexpression of Cav-1 upregulated while knockdown of Cav-1 downregulated the mRNA/protein expression of VM-associated genes including Akt and hypoxia-inducible factor 1 $\alpha$  (HIF-1 $\alpha$ ), respectively, suggesting that the Akt signaling and HIF-1 $\alpha$  may be involved in Cav-1-induced glioma cell proliferation and VM formation. **Conclusion:** Collectively, our study identifies Cav-1 as an important regulator of glioma cell proliferation and VM formation, contributing to glioma development and progression.

## Background

Glioma is the most common malignant primary tumor in the central nervous system, posing a considerable threat to human health [1]. Despite the recent advances in standard treatment options, including surgery, radiation therapy, and chemotherapy, the median overall survival in patients with glioma remains as low as 15 months [2], which highlights the necessity of developing effective therapeutic strategies against glioma. Angiogenesis is a complex process involving formation of new blood vessels that can provide tumor tissues with oxygen and nutrients, thus playing a critical role in glioma growth and metastasis [3]. Targeting angiogenesis has been an US Food and Drug Administration-approved therapeutic strategy for glioma treatment since 2004[4]. However, drug resistance or high rates of relapse greatly limit the clinical application of currently available angiogenesis inhibitors in glioma therapy[5]. Therefore, identifying new therapeutic targets is urgently required for developing potential drugs against glioma.

Vasculogenic mimicry (VM) was first reported in 1999 by Maniotis *et al* as a non-endothelium-dependent vasculature composed of tumor cells and a basement membrane which allows blood plasma and red blood cells to flow in [6]. VM serves as an irrigation system for tumor cells to meet their increasing metabolic and nutrient demands. Existence of VM can be evidenced by Periodic acid–Schiff (PAS) staining due to high abundance of laminin, proteoglycans, heparan sulfate and collagens in the extracellular matrix of tumor cells [7, 8]. CD31<sup>+</sup>/PAS<sup>+</sup> staining is regarded as the golden standard for

tumor cell-lined VM [6, 9-12]. Previous studies demonstrated that VM is correlated with the degree of tumor malignancy and prognosis in patients with glioma [7-8]. Hypoxia resulting from antiangiogenic therapy in glioma may induce VM (compensatory neovascularization) to counteract the hypoxic environment within the tumor, leading to resistance to antiangiogenic therapy [13]. Thus, identifying the genes and signaling pathways implicated in VM formation is needed to develop the effective therapeutic options for glioma.

Human caveolin-1 (Cav-1), a principle structural protein of caveolae, has been shown to act as either a tumor promoter or suppressor depending on the tissue type [14-17]. In glioma, Cav-1 exhibits a tumor suppressive role both *in vitro* and *in vivo* through inhibiting TGF $\beta$ /SMAD pathway or activating apoptosis. On the other hand, Cav-1 was also found to be upregulated proportionally to glioma grades, which suggests a promotive role of Cav-1 in glioma progression [18-20]. Therefore, the function of Cav-1 in glioma development remains controversial. Stenzel *et al*/has reported that, in uveal melanoma, Cav-1 expression is correlated with PI3K activity and VM [21], suggesting that Cav-1 may induce VM formation through the PI3K/Akt signaling cascade. In hepatocellular carcinoma and renal cell carcinoma, Cav-1 is induced by hypoxia via hypoxia-inducible factor 1 $\alpha$  (HIF-1 $\alpha$ ), suggesting a possible role of Cav-1 in tumor angiogenesis [22, 23]. However, the expression pattern of Cav-1 and the relationship between Cav-1 and VM in glioma remain unclear.

In this study, we examined the expression of Cav-1 and VM formation in glioma tissues. The correlations between Cav-1 and VM in glioma patients as well as between Cav-1 expression/VM formation and the clinicopathologic characteristics were determined. The effects of Cav-1 overexpression and knockdown on glioma cell proliferation and VM formation were also investigated. Taken together, our study indicated that Cav-1 regulates the expression of HIF-1 $\alpha$  and the activation of the Akt signaling pathway in glioma cells, suggesting that Cav-1-dependent Akt pathway signaling and HIF-1 $\alpha$  expression may be involved in aberrant VM formation in glioma.

## Methods

### Patients and samples

Tissue samples were obtained from 94 patients with primary glioma undergoing surgical resection at the Department of Neurosurgery, The First Affiliated Hospital of Sun Yat-Sen University, Guangdong, China from January 2010 to July 2014. No patients received chemotherapy or radiotherapy prior to surgery. Final diagnosis was confirmed by two independent pathologists and graded according to the 2016 World Health Organization grading system for central nervous system tumors. Four normal brain tissues were collected from patients with hernia during surgical decompression. All tissue samples were fixed in 4% neutral buffered formaldehyde at 4°C followed by paraffin embedding. The inclusion of patients in this

study was unbiased and was only dependent on the availability of tumor materials and clinical follow-up data. The follow-ups were terminated in July 2017. This study was approved by The Ethics Committee of Sun Yat-Sen University and was in accordance with the Declaration of Helsinki. Written informed consent was obtained from each patient.

### **Immunohistochemical (IHC) staining**

Paraffin-embedded tissue sections (4- $\mu$ m thick) were deparaffinized and rehydrated followed by IHC staining for glial fibrillary acidic protein (GFAP), Cav-1, or CD31. For antigen retrieval, the sections were heated in 1 mM EDTA (pH 8.0) for 15min. The sections were then blocked with goat serum followed by incubation with anti-GFAP (Abcam, Cambridge, MA, USA), anti-Cav-1 (Abcam, Cambridge, MA, USA), or anti-CD31 (Abcam, Cambridge, MA, USA) at 4°C overnight and with horseradish peroxidase (HRP)-conjugated secondary antibody (Abcam, Cambridge, MA, USA) at room temperature for 30 min. Normal IgG was used as a negative control. Finally, the sections were stained with diaminobenzidine and the nuclei were counterstained with hematoxylin. An Olympus IX81 fluorescence microscopy (Olympus, Japan) was used for visualization and brown staining was considered positive. The results were evaluated by two independent pathologists in a blinded manner. Cav-1- or CD31-positive cells with brown staining were counted in five randomly selected fields in each section at 400 $\times$  magnification. The mean number of Cav-1-positive cells was calculated (13 Cav-1-positive cells per field). Therefore, a mean number < 13 was considered low expression whereas a mean number  $\geq$  13 was considered high expression. Representative images (magnification  $\times$ 400) were acquired using a XDS-100 Caikang microscopy (Caikang, Shanghai, China).

### **CD31/PAS double staining**

Following IHC staining for CD31, the sections were exposed to 1% sodium periodate for 10 min, rinsed with distilled water for 5 min, and then incubated with PAS in dark at 37°C for 15 min. The sections were then counterstained with hematoxylin and the results were visualized at 400 $\times$  magnification using an Olympus IX81 microscope. CD31 staining (brown) represents blood vessels in tissues, whereas CD31-negative/PAS-positive (light Purple) staining represents the wall of the VM channels. The number of VM channels was counted in randomly selected 5 fields in each section. The average number was calculated (1.4/field). VM number < 1.4 per field was defined as low, while  $\geq$  1.4 was defined as high.

### **Cell culture and treatments**

Human malignant glioma cell lines U251 and human umbilical vein endothelial cells (HUVECs) were obtained from the Cell Bank of Type Culture Collection of Chinese Academy of Science (CBTCCAS;

Shanghai, China). These cell lines were authenticated by DNA fingerprinting, isozyme detection and cross species checks. All cell lines were maintained in Dulbecco's Modified Eagle Medium (DMEM; Hyclone Cat.No.SH30023.01B, Logan City, Utah, United States) supplemented with 10% fetal bovine serum (FBS; Hyclone Cat.No.SH30087.01, Logan City, Utah, United States) at 37°C in a humidified incubator with 5% CO<sub>2</sub>.

### Generation of glioma cell lines with Cav-1 silencing or overexpression

Small interfering RNA (siRNA) targeting Cav-1 (siCav-1) was purchased from Sigma (Shanghai, China). The sequences of siCav-1 were 5'-CCCUAAACACC UCAACGAUdTdT-3' (sense) and 5'-AUCGUUGAGGUGUU UAGGGdTdT-3' (antisense). The sequences of negative control siRNA (siNC) were 5'-UUCUCC GAACGUGUCACGUTT-3' (sense) and 5'-ACGUGACACGUUCGGA GAATT-3' (antisense).

The coding sequence of human Cav-1 was amplified using the primers 5'-ccgctcgagATGTCTGGGGGCAAATACGTAG-3' (forward) and 5'-cggggtaccTTATATTTCTTTCTGCAAGTTGATGC-3' (reverse), and was inserted into the *XhoI* and *KpnI* sites of linearized pEGFP-C3 vector (Clontech Laboratories, CA, USA) according to the manufacturer's instructions. The recombinant expressing vector pEGFP-C3-Cav-1 was sequenced by BGI Corporation (Shenzhen, China) to confirm the cloned sequences.

U251 cells were seeded in a six-well plate at a density of  $5 \times 10^5$  cells/well and grown overnight. pEGFP-C3-cav-1 or siCav-1 was transfected into U251 cells using Lipofectamine™ 2000 (Invitrogen, Carlsbad, CA, USA) following the manufacturer's instructions. Empty vector pEGFP-C3 and the vector expressing siNC were used as negative controls. After 48–72 h of transfection, the mRNA level of Cav-1 was determined using quantitative real-time PCR (qPCR).

### Tubule formation assay

Tubule formation was evaluated using a Matrigel (BD Biosciences, CA, US)-based three-dimensional (3D) culture model. Briefly, 50 µL of Matrigel was added into each well of 96-well plates and allowed to polymerize at 37°C for 30 min. HUVECs or U251 cells were trypsinized, resuspended in serum-free medium, and seeded onto the Matrigel layer at a density of  $2 \times 10^4$  cells per well. After 6 h of incubation at 37°C, the images of each well were captured using an Olympus BX61 phase-contrast fluorescence microscope (magnification  $\times 100$ ). Four randomly selected areas of vascular network meshes in each well

were measured using Image J software (NIH, Bethesda, MD, USA). All experiments were performed in triplicate.

### **RNA extraction and qPCR**

Total RNA was isolated from tissues or cells using Trizol (Invitrogen, Carlsbad, CA, USA) according to the manufacturer's protocol. The residual DNA was removed using DNase I (Roche, Indianapolis, IN, USA). 2 µg of RNA was reversely transcribed to synthesize cDNA using a M-MLV Reverse Transcriptase Kit (Thermo Fisher, Rockford, IL, USA). The cDNA was amplified using SYBR Green qPCR Master Mix (Thermo Fisher) in an ABI 7300 system (Applied Biosystem, Foster City, CA, USA) following the manufacturer's instruction. The relative mRNA level of Cav-1, HIF-1α, or Akt was calculated by normalization to that of 18s. The PCR primers were as follows: Cav-1, 5'-CACCTAAGCTGCACAGTTCC-3' (forward) and 5'-GGCT GCCTCCTAATTCTTCC-3' (reverse); 18s, 5'-CCTGGATACCG CAGCTAGGA-3' (forward) and 5'-GCGGCGCAATACGAATGCCCC-3' (reverse); AKT1, 5'-ATCGCT TCTTTGCCGGTATC-3' (forward) and 5'-CTTGGTCAGGTGGTGTGATG-3' (reverse); HIF-1α 5'-GTGGATTACCACAGCTGA-3' (forward) and 5'-GCTCA GTTAACTTGATCCA -3'(reverse).

### **Western blot analysis**

Cell lysates were obtained from U251 cells or grounded tissue samples using RIPA buffer containing 1% phenylmethylsulfonyl fluoride. The protein concentration was determined using a BCA protein assay kit (Beyotime). Equal amounts of total protein were separated in 10% SDS-polyacrylamide gels and then transferred onto polyvinylidene difluoride membranes. The membranes were blocked with 5% skim milk for 1 hour followed by an incubation with primary antibody against Cav-1, Akt, HIF-1α or GAPDH (Abcam, Cambridge, MA, USA) at 4°C over night. The membranes were then incubated with HRP-linked secondary antibodies (1:5,000; Beyotime) for 1 h. The protein bands were visualized using enhanced chemiluminescence assay (Thermo) and exposed to X-ray films. The results were scanned and quantified using Image J software.

### **Cell proliferation assay**

Cell proliferation assay was carried out using cell counting kit-8 (CCK-8; Dojindo Laboratories, Japan) following the manufacturer's protocol. Briefly, U251 cells were seeded into 96-well plates at a density of 2000 cell/well and transfected with siRNA. 10 µL of CCK-8 solution was added into each well at 0, 24, 48 or 72 h after transfection followed by an incubation at 37 °C for additional 1 h. The absorbance was measured at 450 nm using a microplate reader (Bio-Rad).

## Statistical analysis

Statistical analysis was performed using SPSS 22.0 (SPSS, IL, USA) or GraphPad Prism 6 (GraphPad, CA, USA). The association between CAV-1 and VM was examined by Spearman analysis, and the differences of clinicopathological variables were analyzed with  $\chi^2$ -test. Statistical comparisons among groups were performed using Student's *t* test and ANOVA. Data were expressed as the mean  $\pm$  standard error of the mean. All experiments were repeated independently at least three times.  $P < 0.05$  was considered statistically significant.

## Results

### Cav-1 expression/VM formation are correlated with glioma grade and overall survival

To determine the expression pattern of Cav-1 in glioma, we performed IHC staining of Cav-1 protein in glioma tissues of 94 patients with primary glioma. As shown in Table 1, Figure 1a and 1b, Cav-1 expression was significantly upregulated in high-grade gliomas (HGG) compared with low-grade ones (LGG), as evidenced by dramatically increased Cav-1-positive tumor cells in HGG compared with those in LGG ( $21.30 \pm 1.676$  vs.  $8.345 \pm 1.021$ ,  $p < 0.001$ ). In addition, CD31/PSA co-staining showed more VM channels in HGG than LGG ( $3.224 \pm 0.3600$  vs.  $1.108 \pm 0.2577$ ,  $p < 0.001$ ), suggesting that the VM-forming ability was remarkably enhanced in HGG compared with LGG. The abundant expression of GFAP in the cells surrounding the VM channels confirmed the cells as glial tumor cells [24, 25]. To further evaluate the potential prognostic value of Cav-1 and VM formation in glioma, we determined the association between Cav-1 expression/VM formation and glioma patient survival time using Kaplan–Meier (KM) analysis and log-rank test. As shown in Figure 1c, both high Cav-1 protein expression and VM-forming ability were significantly correlated with shortened survival in glioma patients, suggesting that upregulation of Cav-1 or VM formation was associated with poor prognosis in glioma. Interestingly, patients with

Cav-1 overexpression and increased VM formation in combination had shorter survival time than those with Cav-1 overexpression or increased VM formation alone or Cav-1 downregulation and inhibited VM formation in combination, suggesting a synergistic effect between Cav-1 expression and VM formation on glioma development and progression.

### Cav-1 expression and VM formation are positively correlated with each other and both are associated with the clinicopathologic characteristics in glioma patients

To further explore whether there is a correlation between Cav-1 expression and VM formation in glioma, we performed a correlation analysis and found that VM formation was positively correlated with Cav-1 expression (Figure 2). We next sought to determine whether Cav-1 expression/VM formation is associated with clinicopathologic characteristics in patients with glioma. As shown in Table 1, the presence of Cav-1 or VM was not correlated with age, sex, or tumor diameter in these 94 glioma patients. Notably, both Cav-1 expression levels and the VM-forming ability were positively correlated with the presence of cystic tumor ( $P = 0.000$  and  $0.028$ , respectively), WHO grades ( $P = 0.000$  for both), and survival at 16-month interval ( $P = 0.007$  and  $0.002$ , respectively) using multivariate analyses. These results indicate that Cav-1 expression/VM formation are associated with glioma progression and prognosis.

### **Cav-1 promotes tumor cell proliferation and vascular formation in glioma**

To determine whether Cav-1 functions in glioma development and progression, tumor cell proliferation, HUVEC tubule formation, and VM formation were examined using vectors expressing Cav-1 or siCav-1 (see Figure S1) to overexpress or knock down Cav-1 in U251 glioma cells, respectively. The transfection efficiency was shown in Figure 3A and B. We found that Cav-1 overexpression significantly promoted while Cav-1 knockdown significantly inhibited U251 cell proliferation at 48 h and 72 h after transfection compared with the control groups (untreated and siNC-transfected cells) (Figure 3C). In addition, 3D culture showed that the conditioned medium from Cav-1 overexpressing-U251 cells significantly increased tubule formation in HUVECs compared with the control groups. Cav-1 overexpression also significantly promoted VM formation in U251 cells. Opposite effects were observed in Cav-1-deficient U251 cells (Fig. 3D and E). Taken together, these results demonstrate that Cav-1 promotes tumor cell proliferation and vascular formation in glioma, contributing to glioma development and progression.

### **Cav-1 regulates the expression of AKT and HIF-1 $\alpha$ .**

To investigate the molecular mechanism underlying the promotive role of Cav-1 in VM formation in glioma, qPCR and Western blot analysis was performed to examine the expression of VM formation-associated Akt and HIF-1 $\alpha$ <sup>18</sup>. As shown in Figure 4A and B, both mRNA and protein levels of Akt and HIF-1 $\alpha$  were significantly elevated by Cav-1 overexpression but suppressed by siCav-1 in U251 cells, suggesting that Akt and HIF-1 $\alpha$  may be involved in Cav-1-induced glioma cell proliferation and VM formation.

## **Discussion**

VM is a non-endothelium-dependent vasculature to complement the endothelium-dependent vessels in providing oxygen and nutrients for malignant tumor cells. Although it has been widely investigated in the

pathology of glioma which is characterized by increased microvasculature in tumor tissues [26, 27], the molecular mechanism governing VM formation in glioma remains largely unknown. Our previous study has shown that Cav-1 and HIF-1 $\alpha$  play important roles in the progress of glioma, and both of them are significantly associated with glioma prognosis (under review). Considering that Cav-1 contributes to VM formation through the PI3K/Akt signaling cascade in uveal melanomas[21], we hypothesized that there might be an association between Cav-1 and VM in glioma.

In the present study, Cav-1 expression and VM formation were examined by immunohistochemistry and CD31/PAS double staining, respectively, in human glioma tissues. The results demonstrated the presence of VM in glioma, which is consistent with previous studies [28, 29]. We also found that Cav-1 expression and VM formation were significantly upregulated in HGG compared with LGG, and both of them were significantly correlated with shortened survival in glioma patients, suggesting Cav-1 or VM formation as a prognostic indicator in glioma. These findings are consistent with previous research demonstrating that patients with VM-positive gliomas survived a shorter period of time than those with VM-negative gliomas [30], suggesting that VM formation is accompanied by increasing malignancy and higher aggressiveness. Therefore, targeting VM is a promising therapeutic strategy for glioma therapy. Since Cav-1 upregulation and VM formation are both correlated with glioma grades and outcomes, we next sought to investigate whether there is a correlation between Cav-1 and VM. Indeed, VM formation was found positively correlated with Cav-1 expression in glioma tissues, and patients with Cav-1 overexpression and increased VM formation in combination had poorer prognoses than other patients, suggesting a synergistic role of Cav-1 and VM in glioma progression. To elucidate the causal relationship between Cav-1 and VM, gain- and loss-of-function analyses were conducted in U251 glioma cells. The results showed that Cav-1 is essential for U251 cell proliferation and VM formation, which is in agreement with the findings in uveal melanoma[21].

Hypoxia is an universal feature of growing solid tumors because of their high demands for oxygen and nutrients caused by cell proliferation [31]. Previous studies have shown that hypoxia induces HIF-1 $\alpha$  and HIF-2 $\alpha$ , which stimulates the formation of tumor vasculatures, including angiogenesis and VM formation, through vascular endothelial growth factors[32]. In this study, to further understand the effect of Cav-1 on VM formation, the expression level of HIF-1 $\alpha$  was evaluated. We found that Cav-1 was an upstream regulator governing the expression of HIF-1 $\alpha$  in glioma cells, which suggests a promotive role of Cav-1/HIF-1 $\alpha$ /VM axis in glioma development. These data, together with a previous finding demonstrating that hypoxia induces HIF-1 $\alpha$ -dependent upregulation of Cav-1 expression in hepatocellular carcinoma [23], suggest a functional interplay between Cav-1 and HIF-1 $\alpha$  in tumors in the event of hypoxia. Further investigation is needed to explore the downstream signaling pathway of this interplay. Moreover, based on the findings that Cav-1 expression is correlated with PI3K activity and VM formation in primary uveal melanoma tissues[21], the expression of Akt, the major downstream effector of PI3K [33], was evaluated.

Our results demonstrated Akt as another possible mediator of Cav-1-induced glioma cell proliferation and VM formation, which is supported by the work of Guo *et al*/ showing that the AKT pathway is critically involved in hypoxia-induced VM formation in glioma cells [34]. However, more experiments, like knockdown or inhibition of Akt and HIF-1 $\alpha$  in Cav-1-overexpressing glioma cells, need to be done to evaluate the direct role of Akt and HIF-1 $\alpha$  in glioma VM formation.

## Conclusions

In conclusion, our study suggests that Cav-1 expression and VM formation may correlated with each other and both of them are unfavorable prognostic factors in patients with glioma. Cav-1-dependent expression of HIF-1 $\alpha$  and Akt may be involved in the promotive role of Cav-1 in glioma cell proliferation and VM formation. Thus, anti-VM therapies should focus on Cav-1 or its downstream VM-associated genes to develop more effective drugs to treat glioma.

## Abbreviations

VM: Vasculogenic mimicry

Cav-1: Caveolin-1

HIF-1 $\alpha$ : hypoxia-inducible factor 1 $\alpha$

IHC: Immunohistochemical

GFAP: glial fibrillary acidic protein

siRNA: Small interfering RNA

LGG: low-grade ones

## Declarations

### Ethics approval and consent to participate

This study was approved by The Ethics Committee of Sun Yat-Sen University and was in accordance with the Declaration of Helsinki. Written informed consent was obtained from each patient.

### Consent for publication

Not applicable

### Availability of data and materials

The datasets used and analysed during the current study are available from the corresponding author on reasonable request.

### **Competing interests**

The authors declare that they have no competing interests

### **Funding**

This study was financially supported by The Technology Project of Huangpu District Guangzhou City (201611).

### **Authors' contributions**

WLC and XC carried out the studies, participated in collecting data, and drafted the manuscript. JSW and CXL performed the statistical analysis and participated in its design. WJH and XBW helped to draft the manuscript. All authors read and approved the final manuscript.

The mean number of Cav-1-positive cells < 13 and  $\geq$  13 in each tumor section at magnification 400 $\times$  was defined as low and high expression, respectively. The mean number of VM channels < 1.4 and  $\geq$  1.4 in each

section at magnification 400× was defined as low and high abilities of VM formation, respectively. Multivariate analyses were stratified by the variables. m, month; VM, vasculogenic mimicry.

## Figures

**Figure 1**

Correlation of Cav-1 expression and/or VM formation with human glioma grades and overall survival of glioma patients. (A) Immunohistochemical staining for GFAP (brown, yellow arrow) and Cav-1 (brown, green arrow) and CD31/PAS co-staining for VM channels (light purple, red arrow) in glioma specimens. Tumor tissues were obtained from 94 patients with glioma. Representative images were shown at magnification 40× and 400×. (B) The mean numbers of VM channels (left) and Cav-1-positive tumor cells (right) in low-grade (n = 39) and high-grade gliomas (n = 55), respectively. Data are expressed as the mean ± standard error of the mean. \*\*\*P < 0.001. (C) Kaplan–Meier analyses of overall survival in all glioma patients with differential Cav-1 expression and/or VM formation.

**Figure 2**

The correlation between VM formation and Cav-1 expression in glioma (n = 94).

**Figure 3**

Cav-1 promotes U251 glioma cell proliferation in vitro. U251 cells were transfected with empty vector pEGFP-C3 or the vectors expressing Cav-1, siCav-1, or negative control siRNA (siNC). The transfection efficiency was confirmed by quantitative real-time PCR (qPCR) (A) and Western blot analysis (B). (C) Cell proliferation was measured at time points as indicated using the CCK-8 assay. (D) U251 glioma cells were transfected with pEGFP-C3, pEGFP-C3-Cav-1, siCav-1, or siNC. The conditioned medium was collected at

48 after transfection. HUVECs were plated on Matrigel and incubated with the conditioned medium for 6 h. The transfected U251 cells were resuspended and cultured on Matrigel for 6 h. Images were captured at magnification 40 × and 100 ×, respectively. Representative images are shown. (E) Branch points in randomly selected 3 fields were counted using Image J software. Data are expressed as the mean ± standard error. \*\*\*P < 0.0001 vs untreated cells. n =3. NC, negative control.

**Figure 4**

Cav-1 regulates Akt and HIF-1α expression. U251 cells were transfected with pEGFP-C3, pEGFP-C3-Cav-1, siCav-1, or siNC. The mRNA (A) and protein (B) expression of Akt and HIF-1α were determined by qPCR and Western blot analysis, respectively. \*\*\*P < 0.0001 vs untreated cells. n = ?. NC, negative control; HUVEs, human umbilical vein endothelial cells.
