Abstract

Background: The prevalence rates of childhood obesity are increasing. The current multidisciplinary treatments for (childhood) obesity are effective, but only short term and rather moderately. A possible mechanism to explain the onset and maintenance of childhood obesity is a maladaptive way of regulating high levels of stress and emotions. Therefore, the current RCT-study aims to test the effectiveness of adding an emotion regulation training to care as usual (multidisciplinary obesity treatment) in young inpatients (10-14) involved in an obesity treatment program compared to care as usual alone. The research model for this RCT-study states that when high levels of stress are regulated in a maladaptive way, this can contribute to the development of obesity. Method: The current study will recruit 140 youngsters (10-14 years) that are involved in an inpatient multidisciplinary obesity treatment (MOT) program. After giving consent to participate in the study, youngsters will be randomly assigned, during consecutive waves, to one of two conditions: care as usual (receiving MOT) or intervention (receiving MOT and on top an emotion regulation training). The training itself consists of 12 weekly sessions, followed by a booster session after three and five months. The participants will be tested pre, post and at 6 months' follow-up. We hypothesize that, compared to the control condition, youngsters in the intervention condition will (1) use more adaptive emotion regulation strategies and (2) report less emotional eating, both primary outcome measures. Moreover, on the level of secondary outcome measures, we hypothesize that youngsters in the intervention condition, compared with the control condition, will (3) report a better sleep quality, (4) undergo an improved weight-loss and weight-loss maintenance and (5) experience a better long-term (6-months) psychological well-being. Discussion: This study will add to both the scientific and clinical literature on the role of emotion regulation in the development and maintenance of different psychopathologies, as emotion regulation is a transdiagnostic factor. Trial Registration: The RCT-study protocol is registered at ISRCTN Registry, with study ID 'ISRCTN 83822934'. Registered at 13 December 2017; <http://www.isrctn.com/ISRCTN83822934>

Introduction

Childhood obesity: growing prevalence, multiple consequences and modest treatment success.

Recent prevalence rates collected by the World Health Organization (WHO, 2016) revealed that worldwide 18% of the school-aged children and adolescents (5-19 years) are diagnosed with overweight and 8% with obesity. These prevalence rates indicate a triplication since 1975, demonstrating the growing problem of pediatric overweight and obesity (WHO, 2016). This causes a great concern for both the individual and the community as obesity has high medical and psychosocial consequences, both in the short-term and long-term (Wyatt, Winters, & Dubbert, 2006).

The well-researched and currently golden standard treatment for childhood obesity is the Multidisciplinary Obesity Treatment (MOT). The overall goal of the treatment is to improve the distorted balance between the energy-intake and energy-expenditure by changing the diet and increasing the physical activity (Braet & Van Winckel, 2000; National Institute for Health and Care Excellence, 2014). The

MOT incorporates cognitive behavioral therapy with active involvement of the parents to support behavior change and enhance the psychosocial wellbeing (Braet & Van Winckel, 2000; National Institute for Health and Care Excellence, 2014). Positive effects of the MOT have already been found on weight (body mass index, BMI -0.5 SD), physical fitness and psychosocial well-being (Naets et al., 2017; Oude Luttikhuis et al., 2009). However, the long-term effects of the MOT are still limited, as weight-loss maintenance seems very hard to attain (Al-Khudairy et al., 2017; Braet & Van Winckel, 2000; Mead et al., 2017; Moens, Braet, & Winckel, 2010; Wilfley et al., 2007).

In sum, the high prevalence rates of childhood obesity, the medical, psychological and economic consequences, and the poor long-term treatment effects emphasize the need to study in depth all mechanisms leading to childhood obesity. Herein, also a psychological perspective recently gains attention. An increasing number of studies point to “stress” as an important factor in the development and maintenance of childhood obesity (Aparicio, Canals, Arija, De Henauw, & Michels, 2016; Hemmingsson, 2014; Jaarsveld, A Fidler, Steptoe, Boniface, & Wardle, 2009; O'Connor, Jones, Conner, McMillan, & Ferguson, 2008). For example, families with an obese child experience more stress (Moens, Braet, Bosmans, & Rosseel, 2009) and daily hassles seem to have a significant impact on children's eating behavior (Debeuf, Verbeken, Van Beveren, Michels, & Braet, 2018; O'Connor et al., 2008). However, although the contributing role of stress in obesity is well-studied, it has not led to treatment options so far. Therefore, the present study will bridge this gap by evaluating its role in an RCT-study.

Stress Conceptualization

Stress occurs when a person perceives (goal-related) danger, attaches personal significance to the situation for his or her well-being and when the available coping resources of the person fail to deal with the situation (Lazarus & Folkman, 1986). Next to the cognitive and emotional component, stress also contains a physiological component (Lazarus & Folkman, 1986). The latter can be seen as a related but different indicator of a stress experience (Vanaelst et al., 2012), reflecting the physiological arousal which prepares the person to cope with the stressor by fighting or fleeing and restores homeostasis. There are two main physiological stress systems (Charmandari, Tsigos, & Chrousos, 2005). The first stress system is the hypothalamic-pituitary-adrenal axis with cortisol as the end product. The second stress system is the autonomic nervous system with the catecholamines, adrenaline and noradrenaline as end products, for which heart rate variability (HRV) is used as a non-invasive biomarker to indirectly measure cardiac parasympathetic and sympathetic activity (Malik, 1996).

When stress is successfully managed, the “emotional homeostasis” will return and, in the long run, the emotional stability will not be fundamentally affected (see Figure 1: eustress). Adversely, when the stress is not successfully managed, it leads to enhanced arousal and negative affect like chronic experiences of tension, danger, frustration or rejection (see Figure 1: emotional distress) (Chrousos & Gold, 1992; Hankin & Abela, 2005; Kranner, Minibayeva, Beckett, & Seal, 2010). Emotional distress is associated with psychopathology (Costello, Mustillo, Erkanli, Keeler, & Angold, 2003; Kessler, Avenevoli, & Ries Merikangas, 2001; Merikangas et al., 2010), medical diseases (Rosengren et al., 2004; Rozanski,

Blumenthal, & Kaplan, 1999; Sapolsky, 1999), and obesity (Aparicio et al., 2016; De Vriendt, Moreno, & De Henauw, 2009; Goodman & Whitaker, 2002; Jaarsveld et al., 2009; Midei & Matthews, 2009; Rofey et al., 2010).

A framework for the stress – obesity relationship

For a thorough understanding on how emotional distress may be associated with weight gain and obesity, three processes need to be taken into account (see Figure 1). First, when stress is not successfully managed, this entails a chronic activation of the physiological stress tonus, which results in an elevated cortisol production. Chronic cortisol hypersecretion is directly associated with the accumulation of fat by stimulation of the fat cell growth and dysregulation of the lipolysis. Indirectly, the elevated cortisol level increases the appetite, calorie-consumption and consequently the adiposity (Björntorp, 2001; Charmandari et al., 2005; Peckett, Wright, & Riddell, 2011). Second, emotional distress triggers a low-grade inflammatory process: directly by elevating the cytokine production and indirectly by its association with less sleep, imbalanced diet and less physical activity that subsequently induce inflammation (Hänsel, Hong, Cámara, & von Känel, 2009; Leonard, 2013). This inflammation process may stimulate other hypothalamic pathways, resulting in increased food intake and finally obesity by resistance to the appetite-reducing factors leptin and insulin (Cai & Liu, 2011, 2012). The third mechanism concerns emotional or stress-induced eating, defined as “overeating in response to emotions and stress” (Aparicio et al., 2016; Braet & Van Strien, 1997; Evers, Stok, & de Ridder, 2010). When experiencing stress, people aim to neutralize the stress-related arousal by eating, even in the absence of hunger, as this gives a warm and good feeling in short term. Especially eating comfort food (e.g., highly palatable food which is rich in sugar and fat) is known as reinforcing (Macht, 2008). Moreover, it initiates an automatic learning process (Evers et al., 2010; Macht, 2008; O'Connor et al., 2008), facilitating emotional eating as the preferred behavior when feeling emotionally distressed. This is observed in both normal weight and overweight adults and children (Braet et al., 2008; Nguyen-Rodriguez, Unger, & Spruijt-Metz, 2009; Van Strien, Herman, & Verheijden, 2009). As emotional eating can foster eating beyond the saturation point, it can lead to an increased calorie intake and to overweight or obesity over time (Frayn & Knäuper, 2017; Koenders & van Strien, 2011).

Importantly, the relationship between emotional distress and obesity is not unidirectional but a vicious cycle can be assumed: obesity itself will lead to further emotional imbalance (e.g. physical and psychological wellbeing), which is hypothesized to further induce (a) enhanced cortisol (b) low-grade inflammation and (c) emotional eating (see Figure 1) (Åkerstedt, 2006; Braet & Van Strien, 1997; McCabe & Ricciardelli, 2001; Pulgaron, 2013; Strauss, 2000; Vgontzas et al., 2008; Wardle & Cooke, 2005). Furthermore, excessive body fat maintains directly the low-grade inflammation which may lead to higher stress sensitivity and a maintained emotional imbalance, as inflammatory cytokines from excessive body fat can affect the brain and its stress-related neuro-circuitry, neuroendocrine activity and neurotransmitters (Castanon, Lasselin, & Capuron, 2014; Hryhorczuk, Sharma, & Fulton, 2013).

The above mentioned drastic processes, resulting from unsuccessfully regulated stress highlight the question as to why some people seem able to regulate their stress, while others are unable. Although it might be that some experience more stressors (Moens et al., 2009), it is also plausible that some are less capable to regulate the stress-related emotions, leading to chronic stress experiences. This brings us to the hypothesis that emotion regulation is playing a crucial role in the vicious cycle of obesity (Figure 1).

Emotion Regulation: the missing link?

Emotion regulation (ER) refers to the actions by which individuals try to exert an influence on the emotions they have, when and how they experience and communicate them (Gross, 1998). These actions implicate the use of several ER competences which refer both to ER abilities (e.g. demonstrating compassion) and strategies (e.g., cognitive reappraisal). ER is recently found to affect different psychological problems, such as depression, anxiety, chronic pain and ADHD (Baer, 2003; Helgeson, Reynolds, & Tomich, 2006; Nolen-Hoeksema, Wisco, & Lyubomirsky, 2008; Rood, Roelofs, Bögels, Nolen-Hoeksema, & Schouten, 2009), and is now recognized as a transdiagnostic factor playing a role in the etiology and maintenance of different kinds of psychological problems (Gratz, Weiss, & Tull, 2015). Based on the long-term effects on affect, behavior and psychopathology, Aldao and colleagues (Aldao & Nolen-Hoeksema, 2012; Aldao, Nolen-Hoeksema, & Schweizer, 2009; Gross & John, 2003) suggest a classification in adaptive ER strategies and maladaptive ER strategies. Especially for obesity, studies have found that the association between stress and weight gain is stronger when more maladaptive ER strategies are used whereby ER seems to mediate the stress-eating relationship (Aparicio et al., 2016; Evers et al., 2010; Vandewalle, Moens, & Braet, 2014). Interesting, recent studies also emphasize the need to research adaptive ER strategies, as these are protective factors (Braet et al., 2014). Commonly, in the literature three adaptive ER strategies, “cognitive reappraisal”, “acceptance” and “problem solving” have been researched and are found to be associated with less psychopathology (2009). Moreover, the adaptive ER abilities “acceptance”, “support yourself” and the strategy “analyze and reappraise” are found to be trainable with positive effects in young adolescents (Volkaert, Wante, Vervoort, & Braet, 2018; Wante, Van Beveren, Theuwis, & Braet, 2017). However, next to learning these ER competencies, also the sequence of applying them when feeling stressed is of importance (McRae, Misra, Prasad, Pereira, & Gross, 2011; Ochsner & Gross, 2005). Therefore, Berking and Whitley (2014) combined all these theoretical insights on ER competencies into a conceptual theory and training model on ER in adults, called the Affect Regulation Training (ART). The ART-model is in accordance with the recent literature on ER flexibility, referring to the importance of momentary flexibility in the use of different ER abilities and ER strategies across different stressful contexts taken into account the personal goals (Aldao, Sheppes, & Gross, 2015; Bonanno & Burton, 2013). Interesting, the ART both as a stand-alone intervention and on top of care as usual, is shown effective in clinical and non-clinical adult populations (Berking, Ebert, Cuijpers, & Hofmann, 2013; Berking, Meier, & Wupperman, 2010; Berking & Whitley, 2014; Gottschalk, Bleichhardt, Kleinstäuber, Berking, & Rief, 2015). Currently, our research group is evaluating the ER sequence, based on Berking and Whitley (2014), in a prevention program for children and adolescents in schools (Volkaert et al., 2018), but it is not yet evaluated in the context of emotional eating in a sample of obese children. However, given the evidence for the mediating role and the trainability of ER, we assume that an ER

training will have good effects also for obese children. Therefore, in the preparation phase of the current RCT-study, the feasibility of learning ER abilities and adaptive ER strategies in a population of obese youngsters has been investigated and well-evaluated (Boelens, Debeuf, verbeken, volkaert, & Braet, manuscript in preparation).

Goals and Hypotheses

As in the presence of stress, flexible and adaptive ER is a requisite to achieve eustress and avoid the detrimental pathways to weight (re)gain and obesity, an ER training may empower the current MOT and foster long-term weight loss maintenance (see Figure 1). The present study will therefore examine the effectiveness of a newly developed 12-week ER group training (one training session of two hours per week) on top of the MOT by means of a ~~clustered~~ randomized controlled trial (RCT) in an inpatient treatment center for childhood obesity. It is hypothesized that adding an ER training to the MOT compared with MOT 'as usual' will result in 1) an improvement in ER competencies (assessed by means of self-report questionnaires, idiosyncratic measures and validated with physiological parameters during a lab task) (=primary outcome), 2) less emotional eating behavior (assessed by means of self-report questionnaires and in a stress paradigm), 3) better sleep quality (assessed by means of self-report questionnaires), 4) improved weight-loss and weight-loss maintenance (in terms of adjusted BMI and waist circumference) with associated change in metabolic parameters, and 5) better long-term (6-months) psychological wellbeing (assessed by means of self- and parent report questionnaires). The protocol was registered at ISRCTN Registry, with study ID: ISRCTN 83822934.

Methods

Participants

Participants will be recruited in an inpatient treatment center for obesity in Belgium, *Het Zeepreventorium*, between March 2018 and September 2020. During consecutive waves, recruitment takes place at intake (T0; four months before starting the inpatient treatment), and both the youngsters and one of the parents should participate in the study. Inclusion criteria of the study are (1) 10-14 years old at the start of the inpatient treatment; (2) primary obesity, with minimum 60% overweight at intake in the treatment center (overweight index: (Cole, Bellizzi, Flegal, & Dietz, 2000)) and (3) language proficiency: mastering the dominant language.

Procedure

At recruitment (T0), the youngsters, meeting the inclusion criteria, and at least one of their parents will both receive detailed information from the researcher and the psychologists of the inpatient treatment center. After receiving this information on the study procedure orally and by letter; the youngsters and at least one of their parents fill out an active informed consent. To obtain the target number of participants, N = 140 (power analysis, see below), a two-year-and-a-half recruitment period, March 2018 until September 2020, is necessary. After giving informed consent, participants are randomly assigned (see

Randomization) to one of the two conditions: intervention condition or control condition. In the intervention condition, the ER training sessions will be given by trainers, who were also involved as clinical psychologists in the development of the ER training.

The Ethics Committee of the Ghent University Hospital approved the study design, procedure and data collection. The national laws and the Helsinki Declaration of 1964 will be applied in all data collection procedures.

Study Design

The study design concerns a two-arm ~~parallel~~ randomized controlled trial, evaluating the effects of an emotion regulation training intervention versus a care-as-usual control group. Assessments, in the two conditions, are planned at four time points: after recruitment (T0), before the start of the intervention (T1), after the end of the intervention (T2) and at 6 months follow-up (T3). Primary outcome measures are emotion regulation and eating behavior, more specifically emotional eating. As secondary outcome measures, (1) weight change, (2) psychological well-being and (3) sleep quality are taken into account.

After giving informed consent (T0), both participants and their parents fill out questionnaires assessing the psychological well-being, ER capacities and perceived stress of the child (parent- and self-report) which will be used for descriptive purposes, or as covariates. Next, before the start of the intervention (T1), at the end of the intervention (T2), and at 6 months follow-up (T3), participants will fill out questionnaires on their psychological well-being, sleep quality, ER capacities, eating behavior and perceived stress level; and participate in a stress paradigm. On top, at T1, the participants will also complete the Standard Progressive Matrices-test to determine their overall cognitive ability. Parents of the participants will be asked again to fill out questionnaires on the psychological well-being and the eating behavior of their child at T2 and T3. Moreover, the participants in the intervention condition will be asked to fill out a diary three times a week on their stress level, affect, ER capacities and emotional eating behavior between the ER training sessions. Filling out a diary enables a more momentary inspection on the relationship between the stress level, ER capacities and emotional eating behavior in the naturalistic environment of the participants.

The eligibility, allocation and assessments are visualized in figure 2 and 3.

Randomization

Stratified randomization is a two-stage process, to control for the influence of covariates (baseline characteristics), in the randomization process (Suresh, 2011). In the current RCT-study, both sex and age are identified as potential/ important covariates. Therefore, separate blocks for each combination of the covariates will be generated (e.g. girls 10-12; boys 10-12; girls 13-14 and boys 13-14).

Participants, who will give consent to participate the study, will be assigned to one of the four blocks.

Afterwards, simple randomization, by dice, within each block, to one of two conditions (e.g. experimental vs. care as usual condition) is applied on the individual level (Kernan, Viscoli, Makuch, Brass, & Horwitz, 1999). The dice is thrown by the same researcher in all consecutive waves. Based on our a priori power calculations that 140 participants have to be included, we will recruit participants till each of the blocks has 35 participants.

Primary Outcome Measures

Stress Paradigm

A lab task was developed for assessing stress and emotion regulation on different levels (e.g., respectively cortisol and physiological parameters), consisting of five blocks: (1) assessment of hunger, physical fitness and activity of the last 24 hours (Visual analogue scales (VAS), as confounder for the physiological parameters); (2) attachment to a 16-channel portable system for physiological research (Porti 16-channel-amplifier; TMSi, Twente Medical Systems International, EJ Oldenzaal, The Netherlands) and measurement of 16 minutes' baseline physiology parameters i.e. 8 minutes in a neutral condition (looking at a white cross on a black computer screen), and 8 minutes in a vanilla neutral condition. In the latter, the WALL-E movie (T1) and two different eight-minutes parts of the Denali movie will be used (T2 and T3); (3) A mood induction via validated fragments of 'The Champ' (T1), 'The Lion King' (T2) and 'Father and Daughter' (T3) (Dudok De Wit, 2000; Rottenberg, Ray, & Gross, 2007). Different baseline- and mood induction movies will be used at the different measurement points to prevent a habituation of the participants to the film fragments and to be able to repeatedly install a negative mood. (4) A food-choice task (Leeds Food Preference Questionnaire task, LFPQ task) (Finlayson, Arlotti, Dalton, King, & Blundell, 2011) and (5) a relaxation exercise. VAS will be scored to rate the stress and affect level and cortisol samples will be collected to validate the stress self-reports, at different time points during the stress paradigm (see Figure 4). All the above mentioned measurements (e.g., VAS, physiology parameters, cortisol and the LFPQ task) will be discussed below.

Stress.

Visual Analogue Scales (VAS). During the stress paradigm, the participants will rate their stress and affect level at five different time-points (see Figure 4) on a 100 mm line. The affects participants will rate are: 'bored', 'anxious', 'frustrated', 'sad', 'happy', 'stressed' and 'angry'. Difference scores between the VAS on different time points for different affects will indicate the changes in mood.

Cortisol. To measure stress during the stress paradigm, salivary cortisol will be collected at six time-points (see Figure 4). Salivettes synthetic swabs of Sarstedt, specifically designed for salivary cortisol analysis (Germany) will be used. The Salivettes will be centrifuged for four minutes at 3000 rpm (Jouan CR412 centrifuge) and the filtrates will be stored at -80°C (Michels et al., 2012; Vanaelst et al., 2012). The routine laboratory of the Ghent University Hospital will assay the salivary cortisol by means of a Modular E 170 immunoanalyser system (Roche Diagnostics, Mannheim, Germany) using the Roche Cobas Cortisol assay. (For a more detailed description of this analysis technique, see (van Aken, Romijn,

Miltenburg, & Lentjes, 2003)). Next, the cortisol concentrations from the analysis ($\mu\text{g}/\text{dL}$) will be multiplied with a conversion factor of 27.586, resulting into SI units (nmol/L) (Damjanov, 1998). The difference in cortisol level throughout the five blocks (stress paradigm) will represent the adaptation or maladaptation to the stress, and thus act as a proxy of eustress and distress (see Figure 1).

Emotion Regulation.

Fragebogen Zur Erhebung der Emotionsregulation Bei Kindern und Jugendlichen (FEEL-KJ). The self- and parent report of the Dutch version of the Fragebogen Zur Erhebung der Emotionsregulation Bei Kindern und Jugendlichen (FEEL-KJ) (Braet, Cracco, & Theuwis, 2013; Grob & Smolenski, 2005) assesses emotion regulation competencies in children and adolescents between 8 and 18 years old. The total amount of items is 90, divided in 15 ER competencies, all measured for three emotions: anger, anxiety and sadness. The 15 ER competencies are divided in three categories: adaptive (e.g., cognitive reappraisal), maladaptive (e.g., rumination) and external regulation (e.g., social support). Items are answered on a five-point Likert scale (from 0= not at all to 4= almost always). For the Dutch and Flemish population, representative norms are available (Braet et al., 2013) and a good reliability and validity was found (Cracco, van Durme, & Braet, 2015).

Emotion Regulation Skill Questionnaire (ERSQ). The Dutch version of the Emotion Regulation Skill Questionnaire (ERSQ) (Berking, 2017; Berking et al., 2008) consists of 27 items and assesses nine different ER abilities and strategies, each operationalized in three items: (1) awareness, (2) (physical) sensations, (3) clarity on which emotions were experienced, (4) understand why an emotion occurs, (5) modification/influencing the emotion, (6) acceptance of the emotion, (7) tolerate the emotion, (8) readiness to confront situations and (9) self-support. Items are answered on a five-point Likert scale (from 0= not at all to 4= almost always). Nine subscale scores and one total score for successful ER abilities and strategies can be assessed (Grant, Salsman, & Berking, 2018). Good psychometric qualities were found for the ERSQ, and the questionnaire has been evaluated as reliable and valid (Berking et al., 2008; Grant et al., 2018).

Idiosyncratic Measures. Participants in the intervention condition (MOT + ER training) will be asked to fill out a diary during three days between the ER training sessions. The diary consists of: VAS (from 0 to 100) questioning the amount of stress, negative affect (anxiety, sadness, anger) and positive affect (happy); and five-point Likert scales (from 1= completely not true to 5= completely true) questioning the use of the ER ability 'emotional awareness' and the ER strategies 'distraction, cognitive reappraisal and problem solving' for the three measured negative feelings.

Respiratory Sinus Arrhythmia (RSA). RSA, a physiological indicator of the parasympathetic nervous system, is shown to be an objective assessment of emotional responding and regulation (Beauchaine, 2015; Porges, 1995, 1996; Santucci et al., 2008). RSA is determined by the heart rate acceleration and deceleration during respectively in- and exhalation (Beauchaine et al., 2019; Porges, 1995, 1996), and reflects the parasympathetic influence on heart rate variability (HRV, defined as the variation over time of the period between successive heartbeats) (Acharya, Joseph, Kannathal, Lim, & Suri, 2007; Berntson et al.,

1997). Numerous studies have linked low levels of resting RSA (at baseline) and large reductions in RSA reactivity (after exposure to a high emotionally eliciting stimulus) to psychiatric disorders characterized by emotion dysregulation, such as depression and anxiety (Beauchaine, 2015; Santucci et al., 2008). These findings are confirmed in children, adolescents and adults (Beauchaine, 2015; Calkins, Graziano, & Keane, 2007; Van Beveren, Mueller, & Braet, 2019; Vasilev, Crowell, Beauchaine, Mead, & Gatzke-Kopp, 2009).

To measure RSA, the autonomic responses, more specifically electrocardiogram (ECG), will be recorded, by means of a 16-channel portable system for physiological research (Porti 16-channel-amplifier; TMSi, Twente Medical Systems International, EJ Oldenzaal, The Netherlands) and the software Polybench 1.2 (TMSi). The signals will be digitized with a 1000 Hz-sampling rate and will be processed in ANSLAB software, a computer program written in MATLAB (Blechert, Peyk, Liedlgruber, & Wilhelm, 2016). R-waves will be detected automatically, followed by a visual check and the edit of artifacts. In order to assess the ECG, throwaway Ag/AgCL solid-gel electrodes with a diameter of 55 mm will be attached to two skin sites: at the right upper sternum and under the left lowest rib. Additionally, a ground electrode will be fixed on a ground wristband on the dorsum of the non-dominant wrist. As shown in Figure 4, the physiological measures will be recorded between the start of block 2 and the start of block 5.

Resting RSA will be recorded during 16 minutes' baseline (block 2, see Figure 4). In both the neutral and vanilla neutral baseline condition, only the final five minutes of the ECG recording will be used for further analyses to ensure that the participants are habituated to the laboratory setting which increases reliability (De Witte, Sütterlin, Braet, & Mueller, 2016). *RSA reactivity* will be quantified as the RSA measures during the mood induction video clip (block 3, see Figure 4) and the food choice task (block 4, see Figure 4) minus the baseline RSA (Beauchaine, 2015; Van Beveren et al., 2019).

Emotional Eating.

Dutch Eating Behavior Questionnaire (DEBQ). The self- and parent-report of the Dutch Eating Behavior Questionnaire (DEBQ) (Braet et al., 2008; van Strien, Frijters, Bergers, & Defares, 1986) assesses three eating styles: restrained, external and emotional eating. In this study, only the subscale 'emotional eating' will be taken into account. In total, the DEBQ contains 33 items, of which 11 items belong to the subscale 'emotional eating', rated on a five-point Likert scale (from 1 = never to 5 = very often). For both the DEBQ total and the subscale 'emotional eating', a good reliability and validity has been reported, and the questionnaire is shown to be useful in research with children and adolescents (Braet et al., 2008; Braet, Tanghe, De Bode, Franckx, & Winckel, 2003; Ricciardelli & McCabe, 2001).

Salzburg Emotional Eating Scale (SEES) and the Salzburg Stress Eating Scale (SSES). The Salzburg Emotional Eating Scale (SEES) and the Salzburg Stress Eating Scale (SSES) are developed to measure emotional and stress-related under- and overeating (Meule, Reichenberger, & Blechert, 2018a, 2018b). The self-report questionnaires contain 20 and 10 items, respectively. The items are formulated as emotional and stressful events of which the participant needs to complement the sentence with one of the five-point Likert scale answer alternatives: 1= I eat much less; 2= I eat less; 3= I eat just as much; 4= I eat more and

5= I eat much more. The SEES questionnaire contains a four factor structure with the following four subscales: Happiness, Sadness, Anger and Anxiety. For each subscale a good reliability, internal consistency and validity was found (Meule et al., 2018a). The SSES questionnaire has a one factor structure, and is found to have a good internal consistency (Meule et al., 2018b).

Idiosyncratic Measures. Three items are added to the diary (see idiosyncratic measures above) to measure the effect of eating on the current mood (e.g., 'When I felt bad today, and I would eat something, I would feel less bummed out and miserable'). Participants will answer the items on a five-point Likert scale (from 1= Strongly disagree to 5= Strongly agree). The items are based on the Trait and State General Food- Cravings Questionnaire (G-FCQ-T, G-FCQ-S) (Nijs, Franken, & Muris, 2007).

Leeds Food Preference Questionnaire task (LFPQ). The Leeds Food Preference Questionnaire (LFPQ) task (Finlayson, King, & Blundell, 2008) is a computer-based paradigm designed to assess explicit wanting and liking of food, and implicit wanting of food. The stimuli are 20 food images varying in fat content (high or low) and taste properties (savory or sweet). Based on these dimensions, four categories of food can be separated (High Fat Savory, Low Fat Savory, High Fat Sweet and Low Fat Sweet) including each five food stimuli (Finlayson et al., 2011; Finlayson et al., 2010; Finlayson et al., 2008). In the explicit task, the 20 food items are shown consecutively on the computer screen, with the following two questions: (1) "How pleasant would it be to consume this food on this moment?" and (2) "How much do you want some of this food right now?". The participants rate the items on 100 mm VAS ranging from "Not at all" to "Extremely", by moving the computer mouse. The implicit wanting task consists of a "forced choice methodology". During this implicit task, two food items of different food categories are shown on the screen. In total, 150 trials are presented with the same standardized instruction: "choose the food item you want to eat most right now". In this implicit wanting task, two outcome measures are registered: the frequency of selected food items in each category (range = 0-75; reflecting a relative preference) and reaction times (milliseconds) of every choice (Finlayson et al., 2011; Finlayson et al., 2010; Finlayson et al., 2008). Good psychometric qualities are found and the LFPQ task is widely used in different contexts (Charlot, Malgoyre, & Bourrilhon, 2019).

Secondary Outcome Measures

Weight index and related metabolic parameters.

Adjusted Body Mass Index (AdjBMI). The Adjusted Body Mass Index (AdjBMI) will be used to objectify the weight index of the participants. This means that the BMI will be calculated and based on normative Flemish data (Roelants, Hauspie, & Hoppenbrouwers, 2009) expressed as percentage above the mean, according their age and gender. Cut-off criteria for childhood overweight and obesity, based on age and gender growth charts, are proposed by the International Obesity Task Force (IOTF). These criteria are 25 kg/m² and 30kg/m², respectively (Cole et al., 2000).

Waist Circumference and Waist Circumference-to-height. *Waist circumference* will be measured to 0.1 cm at the level of the iliac crest (Brambilla, Bedogni, Heo, & Pietrobelli, 2013; Janssen, Katzmarzyk, & Ross,

2004). Percentile reference charts for waist circumference have not yet been developed on a European and Belgian level (Nagy et al., 2014). Therefore, z-scores will be used to make the variable age- and gender-independent. *Waist circumference-to-height* (ratio waist circumference on height) will be computed as recent findings suggest that it predicts adiposity better than BMI and waist circumference (Brambilla et al., 2013). Moreover, a cutoff score for waist circumference-to-height is set on 0.5, related to increased health risks in children (McCarthy & Ashwell, 2006).

Biological samples. To later validate or explain some of the observed intervention effects, several biological samples will be collected, e.g. for inflammation analysis. A passive drool saliva sample is taken at the start of the stress paradigm (T1, T2, T3). In a subsample, fasting venous blood and stool samples are collected (T1, T2).

Psychological well-being.

Child Behavior Check List (CBCL) and Youth Self Report (YSR). The Child Behavior Check List (parent-version) and Youth Self Report (child-version) assess emotional and behavioral problems in children and adolescents between 6 and 18 years old (CBCL) and 11 and 18 years old (YSR) (Achenbach & Rescorla, 2001). Both questionnaires contain 118 items that need to be answered on a three-point Likert scale (0= never; 1= sometimes and 2= often). Three subscale scores can be computed for both questionnaires: Total, Internalizing and Externalizing problems. A good reliability and validity has been found for both questionnaires (Achenbach & Rescorla, 2001).

Children's Depression Inventory (CDI). The Children's Depression Inventory (CDI) (Kovacs, 1992; Timbremont, Braet, & Roelofs, 2008) contains 27 items and assesses depressive symptoms in children and adolescents (7-17 years old). Participants need to read three sentences and have to choose the sentence that best describes him/herself during the past two weeks. Scores assigned to the sentences are 0, 1 or 2, with higher scores indicating more depressive symptoms. A lot of empirical research has strongly confirmed the good reliability and validity of the questionnaire (Kovacs, 1992).

Perceived Competence Scale for Children (PCSC). The child (8-12 years) and adolescent (12-18 years) Dutch version of the Perceived Competence Scale for Children (PCSC) (Harter, 1982; Treffers et al., 2002) assesses the self-perception of competence feelings, both positive and negative. The child-version of the PCSC consists of four subscales measured by 28 items: (1) cognitive abilities, (2) physical appearance and activity, (3) social competence and (4) general self-worth. The adolescent-version of the PCSC contains 35 items and includes three additional subscales: (1) sporting competence, (2) close friendships and (3) overall attitude. Acceptable to good test-retest reliability, good internal reliabilities and factor validity have been reported (Granleese & Joseph, 1994; Harter, 1982).

Positive and Negative Affect Scale for children (PANAS-C). The Positive and Negative Affect Scale for children (PANAS-C) (Laurent et al., 1999) measures two trait temperament dimensions, Negative Affect and Positive Affect. Both subscales contain 15 items, existing out of 15 emotions that need to be rated

on a five-point Likert scale (from 1= 'very slightly' to 5= 'very much'). Good psychometric qualities have been reported for this questionnaire (Laurent et al., 1999).

Physical well-being: Sleep quality

Chronic Sleep Reduction Questionnaire (CSRQ). The Chronic Sleep Reduction Questionnaire (CSRQ) (Dewald, Short, Gradisar, Oort, & Meijer, 2012) consists of 20 items to measure sleep reduction, with four subscales: (1) shortage of sleep, (2) irritation, (3) loss of energy and (4) sleepiness. The items are answered on a three-point Likert scale (with 1= no; 2= sometimes and 3= yes). Good psychometric qualities have been reported for the CSRQ. For the four subscales, a good validity and an acceptable to good reliability has been found (Dewald et al., 2012).

Control Variables

We will control for multiple variables, known as important but without specific hypothesis regarding their effect on our outcome variables e.g. eating disorders, medication use, smoking behavior, puberty state, alexithymia and cognitive functioning. First, eating problems, such as loss of control and binge eating are often observed as comorbidities of obesity (Goossens, Braet, & Decaluwé, 2007; Wilson, Nonas, & Rosenblum, 1993), associated with more eating-related and internalizing psychopathology (Goossens et al., 2007). Second, medication use is associated with a lower heart rate variability (Okada, Okada, & Fujii, 2018). Third, smoking behavior can be a confounder in the relation between stress and weight as it is a maladaptive ER strategy. Moreover, smoking can influence the energy imbalance (Zoli & Picciotto, 2012). Fourth, obesity is associated with early puberty onset, initiated by high levels of leptin (Shalitin & Phillip, 2003). Besides, the pubertal development influences the stress regulation by changes in the cortisol axis (McCormick & Mathews, 2007). Fifth, alexithymia is a construct referring to difficulties in identifying and describing emotions (Taylor, Bagby, & Parker, 1999). In addition, alexithymia is associated with difficulties in discriminating between different emotions (Bagby, Parker, Taylor, & Acklin, 1993) and with difficulties in coping with stressful events (Parker, Taylor, & Bagby, 1998). Sixth, cognitive functioning and more specifically executive functioning is shown to play a role in the development and maintenance of overweight and obesity (Goldschmidt, Hipwell, Stepp, McTigue, & Keenan, 2015; Graziano, Calkins, & Keane, 2010).

Eating disorders: Children's Eating Disorder Examination-Questionnaire (Ch-EDEQ).

The Dutch translation of the Children's Eating Disorder Examination-Questionnaire is a self-report questionnaire (CH-EDEQ) (Decaluwé & Braet, 1999; Fairburn & Beglin, 2008; Fairburn & Beglin, 1994) based on the Children's Eating Disorder Examination (Ch-EDE) (Fairburn, Cooper, & O'Connor, 2008). The Ch-EDEQ can be used in children and adolescents from the age of 8 years; and consists of 22 items. The scale assesses three types of eating behavior: (1) objective overeating, (2) objective binge eating and (3) subjective binge eating; and contains four subscales questioning eating disorder psychopathology: (1) restraint eating, (2) eating concern, (3) shape concern and (4) weight concern. Participants need to

indicate how many days during the last month the behavior occurred. Good psychometric characteristics have been reported (Decaluwé & Braet, 2004).

Medication use.

Medication use will be questioned by one item: “Do you use medication?” with two answer alternatives: “yes” or “no”. When the participant answers “yes”, he or she will be asked to specify the type and amount of medication.

Smoking.

Smoking will be questioned by one item: “Do you smoke?” with two answer alternatives: “yes” or “no”. When the participant answers “yes”, he or she will be asked to specify the amount of cigarettes a day.

Puberty state – Tanner’s stage.

The puberty state and sexual maturation will be measured by two self-report questions on hair and genital development. The participants need to choose between five drawings of genitals (corresponding with the five pubertal stages) and need to indicate the drawing that is most associated with his/her own genital development. Good psychometric characteristics have been reported (Schlossberger, Turner, & Irwin Jr, 1992).

Alexithymia: Toronto Alexithymia Scale-II (TAS-20).

The Toronto Alexithymia Scale-II measures alexithymia with 20 items (TAS-20) (Bagby, Taylor, & Parker, 1994). The items are scored on a three-point Likert scale (from 1= not correct for me to 3= correct for me). The questionnaire contains three underlying correlated factors: (1) difficulties in identifying emotions, (2) difficulties in describing emotions to others and (3) an externally orientated thinking style (Parker, Bagby, Taylor, Endler, & Schmitz, 1993). Good internal consistency and validity has been shown in previous research (Bagby et al., 1994).

Alexithymia: Difficulties in Emotion Regulation Scale (DERS).

The Difficulties in Emotion Regulation Scale (DERS) (Gratz & Roemer, 2004) assesses six possible difficulties in ER: (1) lack of awareness of emotions, (2) lack of clarity of emotions, (3) non-acceptance of emotions, (4) limited access to ER strategies, (5) difficulties controlling impulsive behavior when having a negative feeling and (6) difficulties in goal-directed behavior when experiencing a negative feeling. In this study, only the first dimension will be questioned by six items. The participants need to answer on a five-point Likert scale (from 1 =never to 5 = almost always). High internal consistency, good test-retest reliability and a good validity have been found (Gratz & Roemer, 2004).

Cognitive functioning: Behavior Rating Inventory of Executive Functioning (BRIEF).

Executive functioning will be measured by means of the Behavior Rating Inventory of Executive Functioning (BRIEF) parent-report (Huizinga & Smidts, 2010). The parent-report version contains 75 items, divided in seven subscales: (1) inhibition, (2) cognitive flexibility, (3) emotional regulation, (4) initiation, (5) working memory, (6) planning/organizing and (7) monitoring. Respondents need to answer on a three-point Likert scale (0= never, 1= sometimes and 2= often). Good psychometric characteristics have been reported (Huizinga & Smidts, 2010).

Cognitive functioning: Standard Progressive Matrices-test (SPM).

The Standard Progressive Matrices-test will be included to measure the general cognitive ability of the participant. Five blocks of items are shown to the participant. The items are different figures following a certain logic. The participants need to choose the correct figure in a list of six or eight answer alternatives to complete the logic. Each sets starts with easy items which become more difficult throughout the set (Raven, 2003).

Interventions

Inpatient treatment at the Zeepreventorium VZW (MOT). All participants, both in the intervention and control condition, will receive an inpatient Multidisciplinary Obesity Treatment (MOT) during 12 months, starting from July. The primary aim of the MOT is to obtain a healthy body weight by three main therapeutic components: daily physical activity, healthy diet and cognitive behavioral therapy. Also the parents are involved in the treatment (e.g. via psycho-educational moments) (Braet & Van Winckel, 2000).

Emotion Regulation Training. The emotion regulation training is called 'EuREKA', an acronym for 'Emotie Regulatie training voor Kinderen en Adolescenten', a Dutch translation of 'Emotion Regulation training for Children and Adolescents'. The content and structure of the EuREKA-training will be shortly discussed below. Both a manual and a workbook is available.

Theory. As mentioned in the introduction, Berking and Whitley (2014) developed an Affect Regulation Training (ART) for adults, which is well-evaluated in both clinical and non-clinical samples (Berking et al., 2013; Berking et al., 2010; Berking & Whitley, 2014; Gottschalk et al., 2015). Based on this ART, EuREKA has been developed for use in younger age groups, with several adjustments: an adjustment of terms (e.g. simplified wordings for the ER sequence, see Figure 5), child-friendly adapted psycho-education and exercises evaluated as feasible for children and adolescents.

Content. All ER competences will be learned to the participants by means of (1) psycho-education and (2) exercises, both adjusted to the population of children and adolescents. For example, the psycho-education will be given by movie-clips. Also, the exercises related to the different competences have been evaluated already in schoolchildren (Volkaert et al., 2018) and tested in children with obesity (Boelens et al., manuscript in preparation). After every EuREKA-session, the participants will receive homework to exercise the learned competence.

Structure. The EuREKA-training consists of 12 sessions, one session of two hours per week. Participants will be divided in groups of five youngsters, based on their age. The choice for homogenous groups, based on age, has the following reasons: (1) adjustment of the language during psycho-education and exercises is more easy when all children have the same age and (2) examples can be more life-phase oriented. During every EuREKA-session, two trainers will be present: one trainer will focus on the content of the program while the second trainer will monitor the process in the group (e.g., group dynamics, time management). Every EuREKA-session is organized in the same structure to promote predictability and safety. First, every session starts with a short recapitulation of the previous session in which the learned competence and the accompanying homework is discussed. Second, the new competence is introduced and placed into the sequence, positioned upon the previous learned competences. Third, the new competence is learned in depth, which is the biggest part of the training session with psycho-education and exercises on the new skill. Fourth, all learned competences until that session are exercised in the sequence by an imagination exercise. Fifth, the homework of that specific session is explained and the participants receive a little incentive for their co-operation and motivation during the session (see below, motivational processes).

Drop out, Feasibility and motivational processes. Unfortunately, drop-out rates are quite high in treatment of obesity (Skelton & Beech, 2011). Therefore, increasing the motivation is important at the start of treatment, which will be emphasized during every EuREKA-session. Moreover, to raise the motivation in the current study, participants in both the intervention and control group will receive a cinema voucher after completing the stress paradigm before (T1) and after the intervention (T2). Additionally, after every EuREKA-session, the children in the intervention group will receive a little incentive, adjusted to the content of that particular EuREKA-session. To test the feasibility of the ER training, the trainers and the participants will score after every session different components of the training on VAS (0-100 mm). Both the content of the training and the features of the session (e.g., group safety, attitude of the trainer) will be questioned. These insights aim to help understanding the drop-out and to improve the adherence rates (Skelton, Irby, & Geiger, 2014). Moreover, also the treatment integrity of the EuREKA-training will be evaluated. Therefore, all sessions will be recorded and scored on VAS (0-100 mm) by independent raters.

Data analysis

Sample size. To detect a clinical relevant treatment effect in both primary and secondary treatment outcomes, the power analysis was conducted on the AdjBMI index (Jakobsen et al., 2019). To detect a minimal important difference in the in AdjBMI-index (-0.5 BMI points), a power analysis showed that 63 participants in every condition are necessary to obtain a power of 80% at a significance level of .05. As drop-out rates are high in inpatient treatment centers (Skelton & Beech, 2011), we will include 10% more participants. This calculation leads to the inclusion of 70 participants in both the intervention and control condition.

Data Storage. A research data management plan has been formulated, in which the collected data and data storage has been defined. Concrete, the plan defines the location on the computer where the data is

stored and who is responsible for the data.

Analytical plan. In order to solve the problems of non-compliance and missing outcomes, which are iterative complications in an RCT-study, the intention-to-treat (ITT) principle will be used (Gupta, 2011). Multilevel analyses will be used to test the treatment effects, allowing to handle missing and nested data from the two conditions (intervention versus control condition). More specifically, mixed models with fixed effects for condition (intervention versus control condition), time (immediately after intervention and 6 months follow-up) and their interaction, adjusted for baseline will be used.

Discussion

The current RCT-study emphasizes the growing problem of obesity, which is bidirectionally associated with the occurrence of stress (see Figure 1) by three processes: (1) cortisol hypersecretion, (2) low-grade inflammation and (3) emotional eating. A lack of emotion regulation competencies is hypothesized as important intermediate factor. Therefore, the current RCT-study aims to examine the effectiveness of an ER Training on top of a Multidisciplinary Obesity Treatment (care as usual) in inpatient treated youngsters (10-14 years old). The ER Training 'EuREKA' is an innovative intervention program for children and adolescents, based on the evidence-based ART for adults developed by Berking and Whitley (2014). Previously, in this age group, we first tested the program in schools and designed a feasibility study in obese youngsters (Boelens et al., manuscript in preparation; Volkaert et al., 2018). We hypothesize that EuREKA on top of the MOT will result in 1) an improvement in ER competencies, more specifically having more adaptive emotion regulation strategies, 2) less emotional eating behavior, 3) better sleep quality, 4) improved weight-loss and weight-loss maintenance and 5) better long-term (6-months) psychological well-being.

Results of this RCT-study will add to the scientific and clinical literature on the role of ER in the development and maintenance of pediatric obesity. These results will be of importance as the role of ER in the stress-obesity relationship will be explored and elucidated. Moreover, as ER is a transdiagnostic factor and thus of importance in many psychopathologies, this study will add relevant information to the broad psychology literature. An additional important contribution of the current RCT-study are the new therapeutical insights in order to improve the long-term effects of the existing obesity treatments (Al-Khudairy et al., 2017; Mead et al., 2017). If these first RCT-results point out to be promising, future research should replicate these effects and can set the stage for offering the training in a new format (e.g. a digital m-health tool).

A first strenght of the study is the use of a rigourous design, including a care-as-usual control group (MOT), randomization of the participants and six months follow-up measurements to evaluate the effect of the EuREKA-training in an inpatient treatment for obesity (Freedland, Mohr, Davidson, & Schwartz, 2011). A second strenght is the use of different measurement methods (questionnaires, stress paradigm and physiological measures) and informants (youngsters and parents) at all four data collection time-points (T0, T1, T2 and T3). A third strenght is the well-evaluated ART model and training, which has been

the basis for the development of the EuREKA-training that will be used in this study (Berking & Lukas, 2015; Berking & Whitley, 2014). Fourth, including homework in the EuREKA-training is an advantage since it has the potential to increase the feeling of competence of the learned competencies in the training sessions (Hudson & Kendall, 2002).

This study also has some limitations. First of all, there is a passive control group, implicating that we will be unable to control for several aspects such as extra attention, rewards and homework in the intervention group in comparison with the control group. Second, practical obstacles were expected. Therefore, a feasibility study preceding the RCT-study in an inpatient treatment center for obesity was conducted, and practical difficulties concerning the organization, such as planning the extra therapy during school hours was taken into account. However, new unforeseen obstacles can not always be avoided. Second, no double blind paradigm can be used, as the researchers will know who belong the EuREKA-training intervention group. A consequence is a possible contamination in the instructions by the researchers and the participants of the intervention condition trying to perform better (Hawthorne effect) (Hutchison & Styles, 2010). However, this lack is common in educational research trials (Hutchison & Styles, 2010).

Conclusion

The current RCT-study will evaluate an innovative emotion regulation intervention program, EuREKA, in obese children and youngsters (10-14 years) in an inpatient treatment program. When the EuREKA-training is found to be effective, there is a causal proof of ER's role in overweight and such ER intervention can be applied in clinical practice e.g. after translation towards a digital m-health tool.

Trial Status

The recruitment started in March 2018; and will be ended in September 2019. The RCT-study protocol is registered at ISRCTN Registry, with study ID 'ISRCTN 83822934'. Registered at 13 december 2017; <http://www.isrctn.com/ISRCTN83822934>

Abbreviations

ER = Emotion Regulation

LFPQ = Leeds Food Preference Questionnaire task

MOT = Multidisciplinary Obesity Treatment

EuREKA = Emotie Regulatie Training voor kinderen en adolescenten = Emotion Regulation Training for Children and Adolescents.

Declarations

Acknowledgements/ Funding

The Research Foundation 'BOF' (Bijzonder onderzoeksfonds) provides funding for this study. Grant Number: BOF.24J.2016.0007.02 with fund IV1. All the aspects of the protocol paper, the design and writing, are funded by BOF.

Conflict of interest

The authors declare no conflict of interest

Ethics Approval and consent's

See appendices IC.

The Ethics Committee of the Ghent University Hospital approved the study design, procedure and data collection. Participants and their parents will both receive detailed information on the study procedure orally and by letter; and fill out an informed consent.

Consent for publication

Not Applicable

Authors Contributions

We confirm all authors have substantially contributed to the manuscript, have read and approved the manuscript.

eligibility, allocation and assessments

TIMEPOINT**	STUDY PERIOD					
	Enrolment	Allocation	Post-allocation			
	T0	T1 (pre)	T1a	T1b	T2 (post)	T3 (Follow-up)
ENROLMENT:						
Eligibility screen	X					
Informed consent	X					
Allocation		X				
INTERVENTIONS:						
<i>MOT</i>		←————→				
<i>EuREKA-training: Intensive</i>			←————→			
<i>EuREKA-training: booster</i>					←————→	
ASSESSMENTS:						
<i>Weight and psychological parameters</i>	X	X			X	X
<i>Stress Paradigm</i>		X			X	X
<i>Control Variables</i>	X	X				

Psychological parameters are: PSS, FEEL-KJ, ERSQ, DEBQ, SEES, SSES, CBCL, CDI, PCSC, PANAS-C, CSRQ

Stress Paradigm: VAS, cortisol, metabolic parameters

Control variables: Ch-EDEQ, medication use, smoking, puberty state, TAS-20, DERS, BRIEF, SPM

MOT: Multidisciplinary Obesity Treatment

EuREKA = Emotion Regulation Training for Children and Adolescents
