11           **Abstract**

12           This research paper attempts to investigate both the long-run and causality relationship  
13           among electric power consumption (EPC), technological transfer, financial development  
14           (FD), and environmental quality for the Saudi Arabia (KSA) economy from 1980 to 2019.  
15           In doing so, we propose a carbon emission function tested by incorporating multi-steps  
16           techniques such as autoregressive distributed lag (ARDL) has been exploited to determine  
17           the existence of cointegration or no; while vector error correction model (VECM) has been  
18           applied to decide the direction of causality. In this paper we have proposed two proxies of  
19           technological transfer, namely imported technology (MT) and Technical cooperation  
20           grants (TCG). The results indicate the existence of cointegration between the concerned  
21           series. Besides, the existence of a feed-back effect among variables (except TCG) in the  
22           long-run. However, in the short run feed-back effect exists among EPC and EnvQ; MT and  
23           EnvQ; EPC and MT. Thus, the paper provides original visions for policy makers to  
24           encourage the technological transfer by financing and supporting the electric energy sector  
25           which constitutes the main locomotive to improve the environment quality for the KSA.

28 **1. Introduction**

29 In recent decades, climate change due to carbon (CO<sub>2</sub>) emissions is one of the major  
30 environmental, political and economic challenges since it affects the whole world. Thus, it  
31 is disrupting national economies, degrading the environment, affecting lives, changing  
32 weather patterns, rising sea levels, and weather events are becoming more extreme, etc.  
33 (United Nations, 2018). Therefore, improved EnvQ represents an ecological, economical  
34 and sociological issue of importance and concern worldwide. Hence, humanity is required  
35 to think and act responsibly and determine sustainable solutions especially in countries  
36 with highly energy consumption and economic growth. That could be explained as the  
37 production process is conducted by the demand for energy. Whereas this demand in turn is  
38 conducted by demographic developments, level of economic activities, and by  
39 technological and structural changes (Yeager et al., 2011). Nevertheless, efforts to respond  
40 to the progressive energy demand coupled with the mitigation of climate change represent  
41 a hard task for governments that need several technological innovations, FD with a rational  
42 environmental policy.

43 In this paper we will focus on electricity as the main form of final energy used to power  
44 homes, transport, trades, communications and productions. According to Zhang et al.  
45 (2013) the electricity generation is the principal source of carbon, representing more than  
46 40% of global CO<sub>2</sub> emissions that contribute to degradation of the EnvQ. In fact, in the  
47 KSA, growth and exports rely almost completely on industries that benefit from  
48 circumstantial advantages related to power and raw material provision, knowing that these  
49 resources will deplete over time. Furthermore, the Saudi industrial sector is heavily  
50 concentrated in these basic industries, as they represent 56% of GDP and more than 71%.

51 of exports, relying strongly on the KSA circumstantial advantages related to energy. In  
52 addition, the KSA economy aims to achieve significant performance for key factors of  
53 transformative industries such as innovation, ability to attract and retain talents and  
54 government regulations. This situation made the Kingdom fronted to many challenges such  
55 as improving the competitiveness of the electricity sector through restructuring and  
56 exploring power exportation opportunities, increasing the share of the renewable energy  
57 sector in local consumption and enhancing the competitiveness of the energy sector. In the  
58 same time, reducing environmental degradation by creating a friendly climate while  
59 balancing the need for reducing fiscal burden with need for focused incentives; in  
60 particular, reduce electricity consumption, are the main author challenges to the KSA. In  
61 this context, this study aims to investigate the role played by energy specifically EPC,  
62 technological transfer and FD on EnvQ. As well to understand the long-run and the causal  
63 relationships between variables, we applied a multi-steps methodology based mainly on  
64 ARDL and VECM Granger causality approach. This methodology supports to demonstrate  
65 the effects of relevant technology, financial and economic factors to promote the quality of  
66 the environment in the KSA. To the best of our knowledge, there has never been any  
67 endeavors to investigate both the long-run and the interactions among EPC, technological  
68 transfer, FD and EnvQ for the KSA economy.

69 The reminder of this manuscript is organized as below: Section 2 exposes a literature  
70 review on EPC, technological transfer, FD and EnvQ. Section 3 describes data and model  
71 specification. Section 4 provides econometrics methodology for this research paper.  
72 Section 5 reveals and discusses the empirical results. Section 6 recapitulates and endings  
73 by proposing certain recommendations and policy implications.

74 **2. Literature review**

75 The existing environment and energy literature have rarely examined the relationships  
76 among EPC, technological transfer, FD and EnvQ especially in the KSA economy. This  
77 current paper exposes specifically the most relevant studies which are related to our  
78 variables of interest by classified the existent reviews in three research strands. The first  
79 one examines the relationships among EPC, technological transfer and EnvQ. The second  
80 strand investigates the relationships between EPC, FD and EnvQ while the third explores  
81 the associations among FD, technology transfer and EnvQ. As Table1 proves, the  
82 discoveries of these studies are inconclusive.

83  
84 **2.1. EPC-technological transfer-environment nexus**

85  
86 The studies on the relationships among energy, technology and environment has been  
87 the recent trend in the environment and energy literature (Zang et al., 2013; Mariano et al.,  
88 2016; Wang and Wang., 2018; Pang and Tao, 2018; Kahouli, 2018; Rumayor et al., 2019;  
89 Zafar et al., 2020, Altintas and Kassouri, 2020). To be more specific, Mansouri et al. (2013)  
90 have studied the Saudi electricity sector focused on 18 different forecast figures for CO<sub>2</sub>  
91 emissions engendered by electricity for each year from 2010 to 2025. They have suggested  
92 that Saudi government must declare objectives to reduce CO<sub>2</sub> emissions and to invest  
93 seriously in evolving its own progressions and innovations in energy technologies. In the  
94 case of China, Wang and Wang (2018) have investigated the relationship among MT and  
95 environmental degradation for the period 1980-2011. Based on the ARDL and the VECM  
96 they deduce that imported technologies principally lead to CO<sub>2</sub> emissions in the long-run.  
97 The findings have mentioned the existence of feed-back effects among MT and  
98 environment; energy use and environment. Furthermore, Hodson et al. (2018) have

99 estimated the importance of technology innovation, the fuel prices, and CO<sub>2</sub> emissions on  
100 electric power productions from four U.S. energy-economic models through the year 2050.  
101 Results have shown that realizing innovation aims declines CO<sub>2</sub> emissions owing to  
102 improved energy efficiency.

103 In the same context, Cheng et al. (2019) have studied the associations among the  
104 developments of patents as a technological innovation indicator and CO<sub>2</sub> emissions for 36  
105 OECD countries from 1996 to 2015 by using a panel quantile regression model. Empirical  
106 findings have shown that the coefficient values are not significant and even positive with  
107 CO<sub>2</sub> emissions at different quantile levels. Further, Ali et al. (2019) have investigated the  
108 Kuznets curve of Malaysia over a period of 1985 to 2016 by using the ARDL method. The  
109 results have suggested that improved technology can lead to a cleaner environment.  
110 Consequently, there are bi-directionally linked between environment and energy  
111 consumption as well as between structural changes and technological innovation. In  
112 another paper, Alola et al. (2019) have analyzed the role of renewable energy consumption  
113 and economic growth to ameliorate EnvQ by using ARDL approach to 16 European Union  
114 countries for the period 1997-2014. Empirical results have approved that renewable energy  
115 enhances EnvQ. Focusing in Thailand, Wattana and Wattana (2020) have developed three  
116 scenarios that represent penetration levels of electricity generated from renewable energy  
117 for the period 2018-2037. The results have indicated the importance of technology  
118 innovation in renewable energy that affects positively the electricity generation with a  
119 particular focus on energy security and CO<sub>2</sub> emissions mitigation potentials. Recently,  
120 Sinha et al. (2020) have studied the link between technological innovation and EnvQ in  
121 Middle East and North African (MENA) countries for the period of 1990-2017. They have

122 used the Quantile cointegration and Quantile Autoregressive Granger causality. Empirical  
123 finding indicates mutual dependence among technological progression and ambient air  
124 pollution. More recently, Zameer et al. (2020) have explored the effects of technological  
125 innovation and energy use on CO<sub>2</sub> emissions in the Indian economy during the period  
126 1985-2017 by employing the ARDL and the VECM methods. They have confirmed the  
127 existence of long-term cointegration and energy consumption positively stimulates CO<sub>2</sub>  
128 emissions. Whereas, technological innovation negatively reinforces environment quality  
129 in the long term.

## 130 **2.2. EPC-FD-environment nexus**

131 The relationship between EPC, FD and environment has been well proven this is last  
132 years for instance Sadorsky (2011); Shahbaz (2013); Farhani and Ozturk (2015); Kahouli  
133 and Omri, (2017); Cetin et al. (2018); Kahouli (2018); Xu et al. (2018); Ouyang et al.  
134 (2018); Wang (2019); Eren et al. (2019); Zang (2019); Shahbaz et al. (2020); Acheampong  
135 et al. (2020). Those studies across countries using both panel and time-series data by  
136 incorporating several econometric techniques like as correlation analysis, bivariate  
137 causation, unit root tests, multivariate cointegration, ARDL, VECM, ordinary least square  
138 (OLS), full modified OLS (FMOLS), dynamic OLS (DOLS), generalized method of  
139 moments (GMM), linear and non-linear dynamic panel models. Get started by Shahbaz  
140 (2013) who has explored the nexus among financial instability, environmental degradation  
141 and energy use in Pakistan from 1971 to 2009 by employing ARDL and VECM. The  
142 empirical results have shown that a long-run association among series can be identified as  
143 well as financial instability declines EnvQ. Likewise, Farhani and Ozturk (2015) have  
144 examined the causal relationship among CO<sub>2</sub> emissions, economic growth, energy  
145 consumption, and FD in Tunisia from 1971 to 2012 by applying ARDL and VECM. The

146 empirical findings have indicated that the FD stimulates CO<sub>2</sub> emissions. Besides, Bekhit et  
147 al. (2017) explored the dynamic causal relationships between CO<sub>2</sub>, FD and energy use for  
148 Gulf Cooperation Council (GCC) countries from 1980 to 2011. The results suggest a long-  
149 term causal relationship between CO<sub>2</sub> emissions and FD for all GCC countries except the  
150 United Arab Emirates. Consequently, there is a long-term and one-way direction causality  
151 from carbon emissions to energy consumption for some countries such as the KSA, UAE  
152 and Qatar. Thus, the financial systems of GCC countries should consider environmental  
153 aspects in their decisions while preserving economic growth. In the same line, Kahouli  
154 (2018) has studied the four-way associations linkages among EPC, CO<sub>2</sub> emissions, FD,  
155 R&D and real GDP for the Mediterranean countries from 1990 to 2016 by using SUR,  
156 3SLS, and GMM estimators. Empirical results confirm the existence of strong feedback  
157 effects between variables. In the same context, Xu et al. (2018) have explored the  
158 contribution of FD to environmental degradation in the KSA by applying ARDL and  
159 VECM methods to observe the long-term causal relationship. The results have shown that  
160 FD contributes to the degradation of the quality of the environment and that EPC is the  
161 principal responsible for the environmental degradation in the KSA. Alternatively, the  
162 causality is mutual and bidirectional between long-term CO<sub>2</sub> emissions and FD. In another  
163 perspective, Shahbaz et al. (2020) have examined the link between EPC, FD and  
164 environment by using the Toda-Yamamoto causality test. The finding indicated that FD  
165 raises CO<sub>2</sub> emissions and real GDP is completely associated to environmental degradation.  
166 While, EPC improves the EnvQ. Acheampong et al. (2020) have explored the impact of  
167 the financial market and energy consumption on CO<sub>2</sub> emissions intensity. They have used

168 the GMM technique for 83 countries over the period 1980-201, they have revealed that  
169 financial markets moderate growth and energy to stimulate environment degradation.

### 170 **2.3. Financial development-technological transfer-environment nexus**

171 In the recent literature, there are slight studies trying to investigate our third strand  
172 which purposes to study the link among FD, technology transfer and environment (Khan  
173 et al., 2018; Amri, 2018; Demir et al., 2019; Kahouli, 2019; Ibraheim, 2020; Nguyen et al.,  
174 2020; Avom et al., 2020; Aluko and Obalade, 2020). For instance, Khan et al. (2018) have  
175 examined the link among information and communication technology (ICT), FD, and  
176 EnvQ in emerging countries from 1990 to 2015 by employing mean group (MG) and  
177 augmented mean group (AMG) methods. The empirical findings have shown that the  
178 moderating impact of ICT and FD accelerate the environmental degradation. Likewise,  
179 Amri (2018) has studied the linkage between CO<sub>2</sub> emissions, ICT and FD, in Tunisia from  
180 1975 to 2014 by using ARDL. Empirical results have indicated an insignificant impact of  
181 ICT on CO<sub>2</sub> emissions as a measure of pollution; FD negatively affects the EnvQ. In the  
182 case of Turkey, Demir et al. (2019) have used the ARDL cointegration approach to  
183 examine the relationship between FD, the number of national patents and CO<sub>2</sub> emissions  
184 from 1971 to 2013. The results have revealed that the relationship among the level of CO<sub>2</sub>  
185 emissions and the number of national patents represents an inverted U-curve. Therefore,  
186 FD has positive effects on CO<sub>2</sub> emissions. In another study, Ibraheim (2020) have studied  
187 the nexus between CO<sub>2</sub> emissions, technological innovation and FD in Egypt from 1971 to  
188 2014 by using ARDL, FMOLS, DOLS and Toda-Yamamoto approaches. The empirical  
189 results have shown that technological innovation and alternative energy resources advance  
190 EnvQ, FD deteriorates it. The results from Toda-Yamamoto approach expose that

191 environmental degradation generates technological innovation and FD generates  
192 environmental degradation. In the same order, Nguyen et al. (2020) have studied the effect  
193 of FD, ICT and innovation on EnvQ (proxied by CO<sub>2</sub> emissions) in selected 13 countries  
194 in the G20 from 2000 to 2014 by using FMOLS and Quantile Panel. The empirical findings  
195 have indicated that ICT has an unintended impact on EnvQ through FD. Recently, Avom  
196 et al. (2020) have tested how ICT influences EnvQ in 21 Sub-Saharan Africa (SSA) from  
197 1996 to 2014. They have concluded that ICT has an unintended impact on EnvQ through  
198 energy use, trade and FD. More recently, Aluko and Obalade (2020) have explored the  
199 technology impact of FD on EnvQ in 35 in SSA countries for the period 198-2014 by using  
200 the AMG estimator. The empirical results have mentioned that FD has an unfavorable  
201 technology impact on EnvQ.

202       According to those studies the empirical findings are conflicted. Probably, the principal  
203 reason for these various results derives from the data, econometric approaches and the level  
204 of development of the country in which a study is being carried out. Thus, it is essential to  
205 carry out new exploration concerning the relationship between EPC, technological transfer,  
206 FD and EnvQ.

### 212 3. Data and model specification

#### 213 3.1. Data

214 In order to figure out the nexus between EPC, technological transfer, FD and EnvQ, diverse  
215 proxies have been employed to measure technology and EnvQ in the previous studies. This paper  
216 measures environmental quality (EnvQ) as CO<sub>2</sub> emissions from electricity and heat production,  
217 total (% of total fuel combustion). Likewise, electric power consumption (EPC) determines the  
218 production of power plants and combined heat and power plants (kWh per capita). To identify the  
219 technological transfer, we propose two proxies. The first proxy determines the imported  
220 technology (MT), we utilize computers, communications and other services (% of commercial  
221 service imports) including such activities as international telecommunications; computers. The  
222 second variable as a proxy of the technological transfer is technical cooperation grants (TCG).  
223 Thus, TCG comprise free-standing TCG, which are proposed to finance the transfer of technical  
224 and managerial skills or of technology; and investment linked TCG, which are required to reinforce  
225 the capacity to achieve specific investment projects (current U.S. dollars). Financial development  
226 (FD) defines domestic credit to the private sector (% of GDP). All the data are collected from the  
227 world development indicators (WDI) online database (Appendix.1). The study covers annual data  
228 over the period of 1980-2019 for the KSA economy. The period of the current study is selected on  
229 the accessibility of data.

230 Therefore, table 2 determines the descriptive statistics of these series for the KSA economy. It  
231 denotes that all series are normally distributed as exposed by statistics of Jarque-Bera test. Pairwise  
232 correlation analysis denotes that EPC, TCG and FD are positively associated with EnvQ. Likewise,  
233 TCP and FD are positively associated with EPC. However, the correlation between MT with EnvQ  
234 and EPC are negative. Also, the correlation analysis indicates that TCP and FD are negatively  
235 linked with MT.

236 **Table 2.** Descriptive statistics and correlation matrix.

237 **Notes:** Max., Min. and SD are maximum, minimum and standard deviation, respectively.

238 Data period is 1980-2019 for Saudi Arabia.

239

### 240 **3.2. Model specification**

241 The main purpose of the current study is to investigate the determinants of EnvQ in the case of  
 242 the KSA economy by taking into account the role played by EPC, technological transfer and FD.  
 243 The relationship among the level of EnvQ (CO<sub>2</sub> emissions) as endogenous variable with the  
 244 different exogenous and control variables have long been examined simultaneously  
 245 (Jayanthakumaran et al., 2012; Wang and Wang, 2018; Kahouli, 2018; Shahbaz et al., 2020). The  
 246 present study considers the following EnvQ function:

$$247 \text{EnvQ} = f(EPC, MT, TCG, FD) \tag{1}$$

249 The econometric model for this study is specified as follows:

$$250 \text{EnvQ}_t = \alpha_0 + \alpha_{1t}EPC_t + \alpha_{2t}MT_t + \alpha_{3t}TCG_t + \alpha_{4t}FD_t + \varepsilon_t \tag{2}$$

252 The model transformed to log-linear functional form and stated as below:  
 253

254

$$\ln EnvQ_t = \alpha_0 + \alpha_{1t} \ln EPC_t + \alpha_{2t} \ln MT_t + \alpha_{3t} \ln TCG_t + \alpha_{4t} \ln FD_t + \varepsilon_t \quad (3)$$

256

257 where EnvQ shows, carbon dioxide emissions from electricity and heat production, total (% of  
 258 total fuel combustion), EPC is electric power consumption per capita, MT is imported technology  
 259 measured as computer, communications and other services imports, TCG is Technical cooperation  
 260 grants; the both variables are used as proxies for technological transfer, FD shows domestic credit  
 261 to private sector proxy for financial development.  $\alpha_0$ , t, and  $\varepsilon$  are respectively the fixed country  
 262 effect, the time and the residual term.

#### 263 4. Econometric methodology

264 To study the association among EPC, technological transfer, FD and EnvQ for the KSA we  
 265 propose multi-steps methodology based mainly on ARDL procedure and VECM. The ARDL  
 266 procedure used to estimate the long run and short run relationship presents several advantages:  
 267 First, it can be applied without having the same order of integration or to have the same optimal  
 268 lags for all variables in the system. Second, it is particularly useful for this study because he doesn't  
 269 require large samples or absence of endogeneity between regressors to obtain an efficient  
 270 estimator. Third, the ARDL does not demand to have multiple equations because a single reduced-  
 271 form equation may lead to the same findings. Thus, the ARDL model is expressed as follows:

272

$$\begin{aligned} \Delta \ln EnvQ_t = & \alpha_0 + \sum_{k=1}^n \alpha_{1k} \Delta \ln EnvQ_{(t-k)} + \sum_{k=1}^n \alpha_{2k} \Delta \ln EPC_{(t-k)} + \sum_{k=1}^n \alpha_{3k} \Delta \ln MT_{(t-k)} + \sum_{k=1}^n \alpha_{4k} \Delta \ln TCG_{(t-k)} \\ & + \sum_{k=1}^n \alpha_{5k} \Delta \ln FD_{(t-k)} + \beta_1 \ln EnvQ_{(t-1)} + \beta_2 \ln EPC_{(t-1)} + \beta_3 \ln MT_{(t-1)} + \beta_4 \ln TCG_{(t-1)} + \beta_5 \ln FD_{(t-1)} + \varepsilon_t \end{aligned} \quad (4)$$

274  $\Delta$  represents the first difference and  $\varepsilon_1$  indicates the residual term. The null hypothesis of no  
 275 cointegration among the variables is  $\beta_1 = \beta_2 = \beta_3 = \beta_4 = \beta_5 = 0$ .

276 At the start we will verify the order of integration of the variables by utilizing Augmented Dickey-  
277 Fuller (ADF) test of Dickey and Fuller (1981) and Phillips-Perron (PP) test of Phillips and Perron  
278 (1988). Once proving integration, the next step will be the choice of appropriate criteria; we will  
279 propose Akaike Information Criterion (AIC) for this paper to identify appropriate lag length. The  
280 AIC preserved in view to choose the smallest lag length value and to reduce the loss of a degree  
281 of freedom (Jayanthakumaran et al., 2012 and Ahmed et al., 2015). Likewise, to capture the  
282 dynamic results, an AIC is envisaged more superior and effective as compared to Schwarz  
283 Information Criterion (SIC), which delivers more effective and reliable findings. When the lag  
284 length is designated, we will examine the cointegration among variables, doing so, we will suggest  
285 Johansen cointegration in our study. After confirmation of cointegration among variables, we will  
286 try to examine the long-run and short-run relationship. Furthermore, to verify the constancy of the  
287 model and to confirm finding for policy-maker, this paper applies robustness tests, i.e., Reset test,  
288 ARCH test and LM test. The cumulative sum of recursive residual (CUSUM) and cumulative sum  
289 of the square of recursive residual (CUSUMsq) tests will be used to verify the stability of the  
290 model to recommend policies for implication. Finally, we will turn to examine the direction of  
291 causality among variables. In this context, we will propose the VECM Granger causality approach  
292 in order to determine the direction of causality among EPC, MT, TCG and FD. Consequently, the  
293 empirical equation of VECM Granger causality approach is modeled as follows:

294

$$\begin{bmatrix} \ln EnvQ_t \\ \ln EPC_t \\ \ln MT_t \\ \ln TCP_t \\ \ln FD_t \end{bmatrix} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \alpha_4 \\ \alpha_5 \end{bmatrix} + \sum_{k=1}^n \begin{bmatrix} \alpha_{11k} \alpha_{12k} \alpha_{13k} \alpha_{14k} \alpha_{15k} \\ \alpha_{12k} \alpha_{22k} \alpha_{23k} \alpha_{24k} \alpha_{25k} \\ \alpha_{13k} \alpha_{23k} \alpha_{33k} \alpha_{34k} \alpha_{35k} \\ \alpha_{14k} \alpha_{24k} \alpha_{34k} \alpha_{44k} \alpha_{45k} \\ \alpha_{15k} \alpha_{25k} \alpha_{35k} \alpha_{45k} \alpha_{55k} \end{bmatrix} * \begin{bmatrix} \ln EnvQ_{t-k} \\ \Delta \ln EPC_{t-k} \\ \Delta \ln MT_{t-k} \\ \Delta \ln TCP_{t-k} \\ \Delta \ln FD_{t-k} \end{bmatrix} + \begin{bmatrix} \gamma_1 \\ \gamma_2 \\ \gamma_3 \\ \gamma_4 \\ \gamma_5 \end{bmatrix} * ECT_{t-1} + \begin{bmatrix} \varepsilon_{1t} \\ \varepsilon_{2t} \\ \varepsilon_{3t} \\ \varepsilon_{4t} \\ \varepsilon_{5t} \end{bmatrix} \quad (5)$$

296 When the error correction term  $ECT_{t-1}$  is statistically significant with a negative sign; it is the

297 indication of long-run causality. Furthermore, we employ Wald test to calculate the short-run  
 298 causality.

## 299 5. Empirical findings and discussion

### 300 5.1. Stationary tests

301 This paper applied the ADF and PP unit root tests on the natural logarithms of the variables in  
 302 level and difference forms to explore the relationship between, EPC, technological transfer, FD  
 303 and EnvQ in the KSA. The results described in Table 3 reveal that all the variables of the study  
 304 are stationary at the first difference, which justifies the application of the ARDL technique.

305

306 **Table 3.** Unit root tests analysis.

| Variables     | ADF test           |                    | PP test            |                     | Order of Integration |
|---------------|--------------------|--------------------|--------------------|---------------------|----------------------|
|               | Level              | First difference   | Level              | First difference    |                      |

307 Note: \* indicates the level of significance at 1%.

### 308 5.2. ARDL cointegration tests

309 After proving that all the variables share the same integration properties, we move now to  
 310 investigate the long-run and short-run coefficients by using the ARDL cointegration method. This  
 311 technique is established on two main steps. Beginning with the first step, the long-run relationship  
 312 of Eq. (4) will be clarified by investigating the order of lag. This one will be involved to estimate  
 313 VAR or VECM models that is attained from unrestricted VAR model and by maximized likelihood  
 314 ratio (LR) criterion, minimized final prediction error (FPE), AIC, SIC, and Hannan Quinn (HQ)

315 criteria. The results of this stage lead to conserve the optimal lag which is found to be 1, except  
 316 AIC (Table 4).

317 **Table 4.** Lag length selection criteria for cointegration VAR lag order selection criteria.

| <b>Lag</b> | <b>LogL</b> | <b>LR</b>            | <b>FPE</b>            | <b>AIC</b>          | <b>SC</b>           | <b>HQ</b>           |
|------------|-------------|----------------------|-----------------------|---------------------|---------------------|---------------------|
| <b>0</b>   | 30.350      | NA                   | 1.75e-07              | -1.370              | -1.1526             | -1.293              |
| <b>1</b>   | 159.377     | 216.206 <sup>i</sup> | 6.41e-10 <sup>i</sup> | -6.993              | -5.687 <sup>i</sup> | -6.532 <sup>i</sup> |
| <b>2</b>   | 186.050     | 37.487               | 6.33e-10              | -7.083              | -4.689              | -6.239              |
| <b>3</b>   | 214.787     | 32.620               | 6.39e-10              | -7.285 <sup>i</sup> | -3.802              | -6.057              |

318 <sup>i</sup> Indicates lag order selected by the criterion.

319 Regarding the output of Johansen cointegration (Johansen, 1988; 1991) he has engendered two  
 320 statistics, trace statistic and Eigenvalues. The result of trace statistics and Eigenvalues for the KSA  
 321 assume that there are at least four cointegration relationships that exist among cited variables and  
 322 the null hypothesis of no cointegration can be rejected. The results of the Johansen test are reported  
 323 in Table 5.

324 **Table 5.** Johansen Cointegration Test.

| <b>Hypothesized No. of CE(s)</b> | <b>Eigenvalue</b> | <b>Trace statistic</b> | <b>5% critical value</b> | <b>Prob.<sup>a</sup></b> |
|----------------------------------|-------------------|------------------------|--------------------------|--------------------------|
| <b>None *</b>                    | 0.553             | 83.834                 | 69.818                   | 0.002                    |
| <b>At most 1 *</b>               | 0.466             | 53.191                 | 47.856                   | 0.014                    |
| <b>At most 2</b>                 | 0.341             | 29.309                 | 29.797                   | 0.056                    |
| <b>At most 3</b>                 | 0.264             | 13.450                 | 15.494                   | 0.099                    |
| <b>At most 4</b>                 | 0.045             | 1.788                  | 3.841                    | 0.181                    |

325 \* Trace test indicates 1 co-integrating equations at the 5 % level of significance

326 <sup>a</sup> indicates MacKinnon–Haug–Michelis (MHM) p values of MacKinnon et al. (1999)

327 In the same order, we apply the minimization of AIC and SC (the lag length is used to be 1) to  
 328 find the order of lags. The order of optimal lags is reported in Table 6. For both AIC and SC,  
 329 guides to choosing the same optimal lags (1,0,0,0,1).

330 **Table 6.** Order of optimal lags.

| <b>Number of lags</b> | <b>AIC</b> | <b>SIC</b> | <b>Number of lags</b> | <b>AIC</b> | <b>SIC</b> |
|-----------------------|------------|------------|-----------------------|------------|------------|
| (1,0,0,0,0)           | -1.267     | -0.966     | (1,1,0,1,0)           | -1.282     | -0.895     |
| (1,1,0,0,0)           | -1.345     | -1.000     | (1,1,0,0,1)           | -1.351     | -0.963     |
| (1,0,1,0,0)           | -1.309     | -0.964     | (1,1,1,1,0)           | -1.252     | -0.821     |

|             |               |               |             |        |        |
|-------------|---------------|---------------|-------------|--------|--------|
| (1,0,0,1,0) | -1.190        | -0.846        | (1,1,1,0,1) | -1.335 | -0.904 |
| (1,0,0,0,1) | <b>-1.372</b> | <b>-1.027</b> | (1,1,1,1,1) | -1.251 | -0.777 |
| (1,1,1,0,0) | -1.370        | -0.984        |             |        |        |

331 Italicized and bold statistics denote the minimized AIC and SIC values.

332 In the second step, we estimate Eq. (4) to evince the long-run and short-run coefficients based  
333 on sample data between 1980 and 2019 for the KSA by applying ARDL technique (Table 7). The  
334 empirical results display that the lowest value of the 1-year lag in CO<sub>2</sub> emissions coefficient by  
335 0.220. Furthermore, the results of EPC indicate a long-run and short-run positive effect on CO<sub>2</sub>  
336 emissions. More precisely, a 1% increase in EPC will lead towards 3.048% increase in  
337 environmental degradation. The result is in line with previous studies of Akpan et al. (2012); Bella  
338 et al. (2014); Cetin et al. (2018) and Kahouli (2018) who detected a positive and significant link  
339 among energy and CO<sub>2</sub> emissions in the short-run and the long-run.

340 Likewise, EPC contributes to an important volume of CO<sub>2</sub> emissions in the KSA economy,  
341 which requires policymakers to design a policy that decreases EPC through the provision of  
342 economic incentives for energy saving. However, the coefficient of MT is negative and significant  
343 in the long-run which implies that this variable decelerates environment degradation for the KSA.  
344 Precisely, a 1% increase in MT may decrease CO<sub>2</sub> emissions by 0.174%. These results support the  
345 finding of Kahouli (2018); Wang et al. (2020) and Zameer et al. (2020) since it shows that MT  
346 reduces CO<sub>2</sub> emissions. This is due to the fact that technical progress is able to degrade CO<sub>2</sub>  
347 emissions due to government decisions which incite domestic producers to exploit  
348 environmentally friendly technologies. Therefore, MT in the shape of computers and  
349 communication are environmentally friendly. Otherwise, the modern technology transferred to the  
350 KSA promotes environment quality. The Government of the KSA needs to consolidate input in  
351 R&D and ICT for higher technological strength which will be favorable for protection of the  
352 environment.

353 In addition, the short-run estimate of CO<sub>2</sub> emissions with respect to TCG is negative and  
354 significant at the 10% level. In more details, a 1% increase in TCG may decrease CO<sub>2</sub> emissions  
355 by 0.121%. Nevertheless, in the long-run this coefficient is insignificant indicating that TCG has  
356 no impact on EnvQ, which suggests that TCG is not helpful to the environment of the KSA, and it  
357 does not accompany any contribution in environmental degradation. One probable reason for this  
358 insignificance relation is that the KSA has satisfied their need by funding the transfer of technical  
359 and managerial skills of technology. Finally, the coefficient of FD is positive and significant at the  
360 10% level. It shows that a 1% increase in FD leads to rise CO<sub>2</sub> emissions by about 0.293%. The  
361 results are in line with the findings of Ali et al. (2016); Kahouli (2018); Shahbaz et al. (2020) and  
362 Acheampong et al. (2020) who confirm the existence of a significant relationship between FD and  
363 EnvQ. The development of the financial sector of the Saudi economy plays a very dynamic role in  
364 economic growth which directly affects EPC, and therefore has an environmental degradation  
365 effect.

366 The coefficient of lagged error term i.e. ECM are negative and statistically significant at 5 %  
367 level confirmed that the long-run relationship among EPC, technological transfer (MT and TCG),  
368 FD and EnvQ exist in the case of the KSA economy. In the same order, we apply numerous  
369 diagnostic tests to confirm the stability of the model. The results of these tests are reported in the  
370 lower portion of Table 7. It is established that there is no serial correlation and heteroscedasticity  
371 in the model according to Breusch-Godfrey serial correlation LM test. Moreover, the value of R<sup>2</sup>  
372 for the model shows goodness of fit. The F-statistic which measures the joint significance of all  
373 regressors in the model is statistically significant at the 1% level. The Durbin-Watson statistic is  
374 about two; thus, we can deduce the absence of autocorrelation among residuals (prediction errors)  
375 from a regression analysis. Besides, the results of sensitivity analysis of CUSUM and CUSUMsq

376 tests suggest that the model applied in this paper is well proven. The results of both the graphs are  
 377 exposed in Figs 1 and 2 (Appendix.2.). Both lines plotted within the two straight lines, which  
 378 bound by 5% level of significance. Otherwise, the plots of both statistics are within the boundaries,  
 379 which establish that the pollution model does not violate any assumption. Hence, the model is  
 380 stable and estimated results are trusted and well considered for policy practices.

### 383 5.3. The VECM Granger causality tests

384 The existence of cointegration among series approves that there ought to be at least four causal  
 385 relationships; however, it fails to give its direction. Likewise, the present research investigates the  
 386 direction causal relationship by applying error-correction models based Granger causality tests.  
 387 Such knowledge is useful in making suitable environmental, energy, technological and financial  
 388 policies for sustainable development in the case of the KSA (Fig.1). The results on the direction  
 389 of the long-run and short-run Granger causality are stated in Table 8. Regarding the long-run

390 causality, all the ECT coefficients are negative and statistically significant proposing bi-directional  
391 causal relationships between the variables (except TCG). Otherwise, our results find that there is  
392 an indication of four causal relationships. First causal relationships from EPC, MT, TCG and FD  
393 to the environment. Second causal relationships from environment, MT, TCG and FD to EPC.  
394 Third causal relationships from environment, EPC, TCG and FD to MT. Fourth causal  
395 relationships from environment, EPC, MT and TCG to FD. Nevertheless, an exception is shown  
396 for the TCG equation, which is negative and not statistically significant. This suggests an absence  
397 of long-run causality from the environment, EPC, MT and FD to TCG. This analysis supports the  
398 argument that FD improves EnvQ by prompting the firms to implement advanced technology  
399 which emits less CO<sub>2</sub> emissions during production and/or consumption. These findings are  
400 consistent with Talkudar and Meisner (2001); Shabaz et al. (2013) and Avom et al. (2020) who  
401 suggest that ICT affects CO<sub>2</sub> emissions through energy and FD. Besides, EPC is Granger caused  
402 by FD is consistent with the view studied by Shabaz and Lean (2012) that the financial sector  
403 enables firms to adopt advanced and efficient electric technology during the production and/or  
404 consumption.

405 In the same order, results in Table 8 reveal the evidence of three short-run bidirectional granger  
406 causality confirming the presence of so-called feedback hypothesis among EPC and environment;  
407 MT and environment; EPC and MT. Besides, three short-run unidirectional causal relationships  
408 exist: from FD to EPC, from TCG to MT and finally from environment and TCG to FD. The results  
409 imply that MT is suitable in improving EnvQ by reducing CO<sub>2</sub> emissions. Besides, MT facilitates  
410 the development of smart public transport modes, the reduction in the EPC of household appliances  
411 or even the optimization of the management of lighting, heating and air conditioning in industrial  
412 buildings, etc. In the context of the KSA, it is clear that MT slows down EPC which stimulates a

413 higher quality of environment. Our results are consistent with those of Tang and Tan (2013);  
 414 Kahouli (2018); Zafar et al. (2020) who find a bidirectional causality between EPC and  
 415 technological transfer. In the same context, FD can lead to increased EPC by encouraging  
 416 consumers to borrow money to buy expensive items. Which allows cheaper and easier access to  
 417 financial capital, which can be used on the one hand to develop existing businesses, and on the  
 418 other hand to launch new projects. Consequently, companies will increase their economic activity  
 419 and, subsequently, the demand for energy affecting as a result environment quality (Gaies et al.,  
 420 2019; Acheampong et al., 2020).

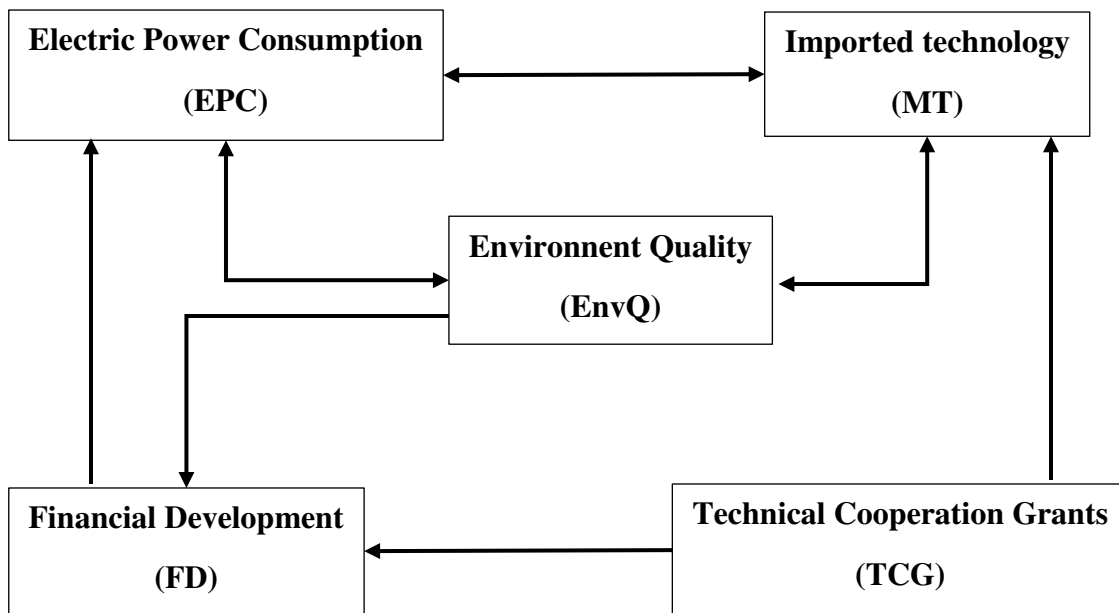

421 **Table 8.** Results of VECM Granger causality analysis.

| Variables                | Direction of causality   |                         |                        |                         |                        | ECT <sub>t-1</sub>    |

| $\Delta \ln \text{FD}$   | 2.660<br>(0.111)**       | 1.100<br>(0.301)        | 3.725<br>(0.061)***    | 8.7E-07<br>(0.999)*     | -                      | -0.041<br>(-1.847)**  |

422 Note: \*, \*\*and \*\*\* show significance at 1%, 5% and 10% respectively.

423 Finally, several policy implications could be derived from this study. First, these results call  
 424 the policymakers and the government of the KSA for more consideration in the subject of  
 425 environmental protection, since electric power and FD cause environmental degradation (in the  
 426 short-run and long-run). Thus, the KSA may impose some pollution control policies such as raising  
 427 the environmental taxes, positioning restraints on activities source of environmental degradation,  
 428 promising academic institutions and environmental projects that may explain how to use and apply  
 429 the methods of environment protection. At this level, policy makers have to promote and

430 consolidate the environment quality, and increase the utilization of cleaner energy sources in order  
 431 to decrease CO<sub>2</sub> emissions and to develop the FD sector. Second, the technological transfer has  
 432 improved the environment quality in the KSA. Government willing to reduce EPC has been clear  
 433 with different implemented legal constraints to use best products in terms of electricity use taking  
 434 into account technological innovation in this field. This shows that the KSA government is already  
 435 on the right path in improving the living standard of the nation by implementing environmental  
 436 friendly projects.

**Fig. 1.** Pairwise Granger causality results.

437

## 438 **6. Conclusion and policy implications**

439 One of the most important strategic objectives of Saudi Arabia 2030 vision is to support efforts  
 440 and commitment to deal with environmental and economic issues. In this context, this paper  
 441 examines the effect of relevant technological and economic factors contributing to promote the  
 442 EnvQ. In the same way, we focus on the effect of the technological transfer (MT and TCG) on  
 443 CO<sub>2</sub> emissions by integrating several variables such as EPC and FD for the KSA for the period

444 1980-2019. For the empirical purpose, our intention was to apply multi-steps techniques to  
445 investigate the relationships between EPC, technological transfer, FD and EnvQ. Precisely, we  
446 have applied the ADF and PP unit root tests in order to verify the order of integration of the  
447 underlying data series which is I (1). Likewise, we have studied and verified the existence of  
448 cointegration among CO<sub>2</sub> emissions and their determinants by using the ARDL cointegration  
449 approach. In the final part of our analysis we have applied the VECM Granger causality to detect  
450 the direction of causality. In the light of our empirical results, we have concluded that there is  
451 mutual dependence between EPC and CO<sub>2</sub> emissions in the short-run and the long-run. Besides,  
452 we have concluded that the development of the financial sector of the KSA plays an important role  
453 which is direct and dynamic for the improvement of environment quality. Accordingly, the  
454 technological transfer affects negatively the EPC. So, EPC has also proven to be an important  
455 factor in increasing CO<sub>2</sub> emissions. It is evident that there is a strong relation among FD,  
456 technologic transfer, EPC and environment for the KSA economy.

457 This result contributes to designing some technological, environmental and financial policies  
458 for the KSA. In fact, the policy makers ought to create and to support environmental protection  
459 and the green economy. Additionally, the importance of FD in the KSA economy increases the  
460 share of the energy sector without harming the environment. We are well aware that the  
461 government is moving towards a non-petroleum economic diversification strategy to have more  
462 investment flows in the energy domain while encouraging the technological transfer. Therefore,  
463 to achieve this, the government is increasingly subsidizing technological projects aimed at  
464 reducing energy consumption and thus having a beneficial effect on the environment. In fact, this  
465 approach makes it possible to maintain environmental stability and to avoid any negative effects.  
466 Likewise, the incorporation of energy efficient technologies into the energy electric segment of

467 the country can be a means of protecting the quality of the overall environment. For this reason,  
468 the KSA aims to conserve electricity or use it more efficiently for consumers. Thus, the  
469 comprehensive approach to energy policy aims to reduce cost disparities through less subsidies to  
470 conventional energy. In this regard, it is necessary to adopt techniques of the cost of energy over  
471 several years such as that provided for in their vision 2030. Indeed, policymakers should seek and  
472 encourage cleaner sources of energy consumption. They should develop policies for the  
473 development of electricity networks in the various cities of the country to achieve energy savings.  
474 The application of this type of policy makes it possible to reduce CO<sub>2</sub> emissions. In addition,  
475 applying a smart tax system at the same time helps prevent damage to the environment. To  
476 conclude, encouraging the technological transfer, facility spillover knowledge, promoting  
477 innovation and consolidating R&D activities by financing and support of electric energy sector  
478 strategies constitutes the main locomotive to improve the environment quality for the KSA.
