Abstract

Objectives: The aim of this ecological study was to investigate what the impact of digital learning due to the COVID-19 pandemic was on the burnout and the overall mental health (MH) of medical students.

Background: During the unprecedent era of COVID-19 pandemic, the majority of countries worldwide adopted very strong measurements. The universities closed their doors and the education continued through digital learning lectures.

Methods: An anonymous questionnaire was administered to all 189 eligible candidates before and during the COVID-19 pandemic. Mental health was assessed via the MH domain of the 36-item Short Form Health Survey (SF-36) and burnout with the Maslach Burnout Inventory – Student Survey (MBI-SS).

Results: Overall response rate was 81.5%. The overall burnout prevalence did not differ significantly between the two periods (pre COVID-19 18.1% vs COVID-19 18.2%). However, the burnout prevalence dropped significantly in year 4 (pre COVID-19 40.7% vs COVID-19 16.7%, p=0.011) whereas it increased significantly in year 6 (pre COVID-19 27.6% vs COVID-19 50%, p=0.01). When looking each MBI-SS dimension separately, we found that emotional exhaustion decreased significantly in year 4 but increased in year 6 and cynicism increased in all years. The overall MH deteriorated significantly between the two periods (pre COVID-19 58.8±21.6 vs COVID-19 48.3±23, p<0.001).

Conclusions: Digital learning in medical studies carries significant risks. Not only the MH deteriorates the cynicism levels increase. Emotional exhaustion increases particularly in final year students, who struggle with the lack of clinical experience just before they start working as qualified junior doctors.

Background

Burnout during medical studies is a phenomenon that increasingly gains attention on education research. Burnout plays a significant role in the overall well-being of medical students and has severe implications for the continuation of burnout during the residency period and even further [1].

During the unprecedent era of COVID-19 pandemic, the majority of countries worldwide adopted very strong measurements. The universities closed their doors and the education continued through digital learning lectures.

The aim of this ecological study was to investigate what the impact of digital learning due to the COVID-19 pandemic was on the burnout and the overall mental health of medical students.

Methods

Study design
The Medical School Undergraduate Program runs for 6 years (three preclinical and three clinical years). In total 189 students are currently enrolled, all of which were invited to take part in the study. Originally the study was designed as a cross-sectional study before the COVID-19 pandemic and, thus, we had a baseline assessment (pre – COVID 19) which took place in January 2020. As the pandemic emerged in February 2020 and a subsequent lockdown and digital learning took place in March 2020 (including no clinical teaching for the clinical years 4–6) we performed a follow-up assessment in May 2020 (COVID-19).

Patients or the public were not involved in the design, or conduct, or reporting, or dissemination plans of our research. The study was approved by the Cyprus National Bioethics Committee. All participants given written informed consent in order to participate.

Assessments

**Mental health (MH)** was evaluated by the MH domain of the 36-item Short Form Health Survey (SF-36) [2]. Students answered the five items concerning their emotional well-being during the last four weeks in a 6-point Likert-type scale, ranging from 1 (all of the time) to 6 (never). Two items (e.g., "Have you been a happy person?") were reverse scored to ensure that a higher item value indicated better mental health. Then scores were transformed in a 0 to 100-point scale and averaged. Higher scores denoted better MH. The instrument showed good reliability for this study (Cronbach's alpha = 0.88).

**Burnout**: The Maslach Burnout Inventory – Student Survey (MBI-SS) was used to evaluate burnout among medical students [3]. Licenses to use MBI-SS were purchased via Mind Garden Inc. MBI-SS is a 16-item tool, with each item being rated on a 7-point Likert-type scale, ranging from 0 (never) to 6 (everyday). These items produce three subscales: exhaustion (EX), cynicism (CY) and efficacy (EF). As suggested by Schutte et al., one particular CY item (“When I’m in class or I’m studying I don’t want to be bothered”) removed because it was shown to be ambivalent and, thus, unsound [4]. The construct and concurrent (i.e. criterion-related) validity and the reliability this instrument were verified. The instrument showed good to excellent reliability for this study (Cronbach's alpha: EX=0.92, CY=0.87, EF=0.84).

Burnout was defined as: a. EX score higher than the 75th percentile (21 for this study) and b. CY score higher than the 75th percentile (5 for this study) or EF lower than the 25th percentile (22 for this study), as previously suggested [5].

Statistical analysis

A database was developed using the Statistical Package for Social Science version 21.0 (Armonk, NY: IBM Corp). Frequencies (%) were used to present data for the burnout prevalence. We applied binomial tests to compare burnout prevalence between the different COVID-19 periods, since medical students between each COVID-19 group were not completely independent neither matched. Within COVID-19 group comparisons for burnout prevalence across the medical years of education were made with chi-square test. Adjusted standardized residuals served to ascertain significant deviations from the expected
frequencies. One sample Wilcoxon signed rank test was applied to compare EX, CY EF, and MH between COVID-19 groups. The level of significance was 0.05. The corrected p value of 0.02 for six comparisons was used for all COVID-19 group comparisons across the medical years of education, according to the Benjamini–Yekutieli method.

**Results**

Of the 189 students, 182 participated to the baseline assessment (pre-COVID 19 response rate 96.%). Of those, 154 participated to the follow-up assessment (COVID 19 response rate 84.6%). Overall 154 (69.5% females, mean age 22.6±4.1 years) medical students participated in both assessments giving an overall response rate of 81.5%.

The overall burnout prevalence among medical students did not differ significantly between the two periods (pre COVID-19 18.1% vs COVID-19 18.2%). However, a significant change of burnout prevalence was found when looking into each academic year separately. In particular, burnout prevalence dropped significantly in year 4 medical students whereas it increased significantly in year 6. (Table 1). When looking each MBI-SS dimension separately, we found that EX decreased significantly in year 4 but increased in year 6, CY increased significantly in all years but year 4 and EF decreased significantly in year 4.

¹Binomial tests

* p≤0.02: Benjamini–Yekutieli corrected level of significance for six comparisons

The overall MH deteriorated significantly between the two periods (pre COVID-19 58.8±21.6 vs COVID-19 48.3±23, p<0.001). When looking into the academic years separately, it deteriorated in all years and
reached statistical significance in years 1, 3 and 6.

Figure 1 summarizes the changes observed in MH, EX, CY and EF.

Discussion

The novelty of our study is that we examined what impact digital learning had in MH and burnout during the medical studies. We were able to perform this study as we had a baseline assessment only few weeks before the announcement of the strict measurements due to COVID-19 pandemic and we managed to reassess the students during the COVID-19 pandemic whilst the University still was offering only live electronic lectures. Our overall response rate was high (81.4%), which strengthens our results. Although there was no significant difference on the overall burnout rate, there were two hidden messages when looking into the dimensions separately.

First, in all years CY levels increased. This dimension of MBI-SS assesses the views of students about their studies. Increased cynicism means that students doubt about the significance and usefulness of their studies and they become less interested or enthusiastic. A prerequisite for becoming a medical doctor is getting clinical experience, which cannot happen through electronic lectures or videos.

Second, different patterns were observed in the EX dimension. The emotional exhaustion reported by the 4th year medical students decreased significantly whereas it increased significantly in the 6th year students. This accounted for the change in the overall burnout rate when looking in each academic year separately; the rate dropped in 4th year whilst it increased dramatically in the final year.

Previous research has shown a consistent pattern of increasing burnout after the initiation of the clinical exercise where students confront patients, disease and death [6 – 12]. In our School, clinical training begins at year 4. When this direct contact stopped as a result of the digital learning we observed a decrease of burnout in those students. Contrary, at year 6 the opposite happened. A possible explanation for this is that those students are one step before becoming doctors. This uncertainty of the subsequent years as a professional along with the lack of clinical experience due to the digital learning just before qualifying are very burdensome.

Conclusion

Our study shows that digital learning in medical studies carries significant risks for the students. Not only the MH deteriorates but the lack of direct interaction with the teachers and the clinical tutors increase the CY levels. Particularly final year students, struggle with the lack of clinical experience just before they start working as qualified junior doctors.
