Research ideas:
If the prime number is continuous, and any pairwise addition can obtain even number continuity, then Goldbach's conjecture is true.
Human even number experiments all get (prime number + prime number).
I propose a new topic: the continuity of prime numbers can lead to even continuity.
I designed a continuous combination of prime numbers and got even continuity.
If the prime numbers are combined continuously and the even numbers are forced to be discontinuous, a breakpoint occurs.
It violates Bertrand Chebyshev's theorem.
It is proved that prime numbers are continuous and even numbers are continuous.
The logic is: if Goldbach conjecture holds, it must be that the continuity of prime numbers can lead to the continuity of even numbers.

Image interpretation: turn Goldbach's conjecture into a ball, and I kick the ball into Goldbach's conjecture channel.
There are several paths in this channel, and the ball is not allowed to meet Goldbach's conjecture conclusion in each path.
This makes the ball crazy, and the crazy ball must violate Bertrand Chebyshev's theorem.
Abstract: Two prime numbers \(\{3, 5\}\).
\(\{3, 5\} \rightarrow \{3+3= 6, \ 3+5=8, \ 5+5=10\} \rightarrow \{6,8,10\}\).
\(\{\{10\}\} \rightarrow (5+5=10 = 3 + 7) \rightarrow 7\) Increased by 7 \(\rightarrow \{3, 5, 7\}\).
Note changes: \(\{3, 5\}\) \(\rightarrow \{6,8,10\}\) \(\rightarrow \{3, 5, 7\}\).
\(\{3,5,7\} \rightarrow \{3+3= 6, \ 3+5=8, \ 5+7=10, 5+7=12, 7+7=14\} \rightarrow \{6,8,10,12,14\}\).
\(\{\{14\}\} \rightarrow (7+7=14 = 3 + 11) \rightarrow 11\) Increased by 11 \(\rightarrow \{3, 5, 7, 11\}\).
Note changes: \(\{3,5,7\}\) \(\rightarrow \{6,8,10,12,14\}\) \(\rightarrow \{3, 5, 7, 11\}\).

The same logic would be: \(\{3,5,7,11\}\) \(\rightarrow \{6,8,10,12,14,16\}\) \(\rightarrow \{3, 5, 7,11,13\}\).
The same logic would be:
\(\{3,5,7,11,13\}\) \(\rightarrow \{6,8,10,12,14,16,18,20\}\) \(\rightarrow \{3, 5, 7,11,13,17\}\).
【 Note: if a prime number is added, \(n\) consecutive even numbers (\(n \geq 1\)) can be obtained.】
Sequential continuation, ...... If you expand infinitely in the above specified mode: \{3, 5, 7, 11, 13, 17, 19, 23,...\}
Get: \{6,8,10,12,14,16,18,20,22,...\}
The above is: the continuity of prime numbers can lead to even continuity. Get: Goldbach conjecture holds.

If it is mandatory: Authenticity stops at an even number \(2n\).
\(\{3, 5, 7, 11, 13, 17, 19, 23,...,p_i\}\) \(\rightarrow \{6,8,10,12,14,16,18,20,22,...,2n\}\).
\(\{3, 5, 7, 11, 13, 17, 19, 23,...,p_i\} \not\rightarrow (2n+2)\).
\(\forall p+\forall p\neq 2n+2 \) It can be proved that: It violates the "Bertrand Chebyshev" theorem.
\(\vdash \{3, 5, 7, 11, 13, 17, 19, 23,...\}
\(\rightarrow \{6,8,10,12,14,16,18,20,22,...\}
Get: Goldbach conjecture holds.

Key words: prime even continuity; Bertrand Chebyshev theorem; Ascending and descending; Extreme law; Mathematical complete induction

0 introduction
Background of the study
Goldbach conjecture\(^{(1)}\): Euler's version, that is, any even number greater than 2 can be written as the sum of two prime numbers, also known as "strong Goldbach conjecture" or "Goldbach conjecture about even numbers".
It was put forward in 1742, and today it has trapped excellent mathematicians of mankind. Is this Goldbach conjecture correct? Or wrong?
Why can't humans find a way to prove or falsify?
It is because human beings do not find the right path by definition, and human beings have
gone astray.

Purpose of the study
Starting with the definition, find out the internal relationship between Goldbach conjecture and mathematical logic,
Confirm Goldbach conjecture or deny Goldbach conjecture.
Prove the distribution law of prime numbers.

The summary of the existing literature proves that the study of Goldbach conjecture is correct.

1 Text: introduction

1.1 Research skills: The whole proof begins with the ascent

1.1.1 Even number generation provisions in this paper
Rule ①: the minimum odd prime number is 3
Rule ②: add two odd prime numbers (any combination of two odd primes).
Rule ③: odd prime number can be quoted repeatedly.
Rule ④: meet the previous provisions, and all prime combination to the maximum (for example, 10 = 5 + 5 must be: 10 = 5 + 5 = 3 + 7,
For another example, the combination of 90 must be: 90 = 43 + 47 = 37 + 53 = 31 + 59 = 29 + 61 = 23 + 67 = 19 + 71 = 17 + 73 = 11 + 79 = 7 + 83).
Rule ⑤: \( P_a + P_b = 2S \), and \( P_b + P_a = 2S \), Delete one and leave only one.

1.1.2 I can quote the minimum odd prime number 3
The results are as follows
\[ 3 + 3 = 6 \]
\[ 5 + 1 = 6 \] (it is stipulated that 1 is not a prime number, which is deleted because it violates regulation 2)
∴ The unique formula: \( 3 + 3 = 6 \). (comply with Rule ④: all prime numbers are quoted to the maximum).
\[ 3 \rightarrow 6 \]

1.1.3 Even number generation provisions in this paper: Get the following
\[ \{3\} \rightarrow (3+3)=6 \]
\[ \{3,5\} \rightarrow (3+5)=8 \]
\[ \{3,5\} \rightarrow (5+5)=10 \rightarrow (3+7) \rightarrow \{7\} \]
\[ \{3,5,7\} \rightarrow (5+7)=12 \]
\[ \{3,5,7\} \rightarrow (7+7)=14 \rightarrow (3+11) \rightarrow \{11\} \]
\[ \{3,5,7,11\} \rightarrow (11+5)=16 \rightarrow (3+13) \rightarrow \{13\} \]
\[ \{3,5,7,11,13\} \]
Look: prime continuous $3 \rightarrow 5 \rightarrow 7 \rightarrow 11 \rightarrow 13$

Look: you get "even numbers are also continuous" $6 \rightarrow 8 \rightarrow 10 \rightarrow 12 \rightarrow 14 \rightarrow 16$

If you let the prime number be infinitely continuous: $3 \rightarrow 5 \rightarrow 7 \rightarrow 11 \rightarrow 13 \rightarrow 17 \rightarrow \ldots$

"Even numbers are also infinitely continuous": $6 \rightarrow 8 \rightarrow 10 \rightarrow 12 \rightarrow 14 \rightarrow 16 \rightarrow 18 \rightarrow \ldots$

A new theorem is obtained: The continuity of prime numbers can lead to even continuity.

If this theorem is proved, Goldbach's conjecture is correct.

1.2 The proof process uses the known prime number,

Continuity of prime numbers:
‘\*’ The theorem of infinite number of primes$^{[3]}$:
① There is no maximum prime;
② After each prime, you can always find an adjacent prime.
‘\*’ Prime numbers have continuity.

Prime number theorem$^{[3]}$ and Bertrand Chebyshev$^{[2]}$ theorem.
By quoting the prime theorem (Each prime has a subsequent adjacent prime.), we obtain the unrestricted continuity of prime numbers, and then generate even numbers according to the requirements of this paper. If the generated even number is infinitely continuous, Goldbach's conjecture is correct.

Use the limit rule to force the even number to terminate at $2n=(Prime) + (prime)$, and the even number $2n + 2=(Prime) +( prime)$ cannot occur.
Conclusion:
If it conforms to mathematical logic, then: Goldbach conjecture is wrong.
If it does not conform to mathematical logic, then Goldbach's conjecture is correct.

2 Text: nouns and definitions

2.1 {Definiton of prime number: prime number refers to the natural number with no other factors except 1 and itself in the natural number greater than 1.} record: (2.1)

2.2 {Extreme law : A may or may not be true. What conclusion can we get if we only prove that A is not true.
\{A \mid A=x.A=y\},(A=x) \Rightarrow (QED). \text{ Take: } A \neq x, \text{ only prove the } A=y \text{ conclusion.}\}

2.3  {\textbf{References cited} $[^{[2]}]$} Bertrand Chebyshev theorem: if the integer $n > 3$, then there is at least one prime $P$, which conforms to $n < p < 2n - 2$. Another slightly weaker argument is: for all integers $n$ greater than 1, there is at least one prime $P$, which conforms to $n < p < 2n$. record: (2.3)

2.4  \{The generation of even and prime numbers in this paper is specified as follows:
In this paper, the even number generation rules: the following five rules are met at the same time.
\begin{enumerate}
\item Only odd primes are allowed as elements.
\item Only two prime numbers can be added. (any combination of two odd primes).
\item Two prime numbers can be used repeatedly: $(3 + 3)$, or $(3 + 5)$, or $(P + P)$.
\item meet the previous provisions, and all prime combination to the maximum (for example, $10 = 5 + 5$ must be: $10 = 5 + 5 = 3 + 7$, For another example, the combination of 90 must be: $90 = 43 + 47 = 37 + 53 = 31 + 59 = 29 + 61 = 23 + 67 = 19 + 71 = 17 + 73 = 11 + 79 = 7 + 83$).
\item Take only one of $(p+a+p+b)$ and $(p+b+p+a)$.
\end{enumerate}

In this paper, the generation rules of prime numbers: the following three rules are met at the same time.
\begin{enumerate}
\item The first odd prime number is 3.
\item Get the prime number from the even number. For example, $3 + 5 = 8$. Prime numbers 3 and 5 are the materials I can cite.
\item Get the prime number from the even number. It must be two prime numbers. For example, $3 + 5 = 8$. In the combination of even number 8, the prime numbers 3 and 5 are the materials I can cite. For example, $1 + 7 = 8$. In the combination of even number 8, I cannot quote prime number 7.
\end{enumerate}
record: (2.4)

A pseudo stop property is obtained in (2.4):

2.41 \{Pseudo stop: Explain first. the first prime number 3, according to the even number generation regulations, gets $3 + 3 = 6$. Even number 6, according to the prime generation regulations, cannot generate 5, because $(1 + 5)$ does not meet the even number 6 in this paper,
cannot generate quality 5. So there is a false stop: only 3, no 5, only 6, no 8. But you can artificially increase prime number 5, and you can also get 8 (3 + 5). So it is a false stop.

Pseudo stop definition:
① the maximum even number among the continuous even numbers composed of k consecutive prime numbers \{3,5,7,11,..., P_1\} is 2n
② \{3,5,7,11,..., P_1\} can meet: \{6, 8, 10, 12, 14, 16, 18, 20,..., 2n\}
③ \{3,5,7,11,..., P_1\} not satisfied: \{2n + 2\}
④ Odd prime \( P_0 \): \( P_0 \not\in \{3,5,7,11,\cdots, P_1\} \), satisfying: \( 2n + 2 = P_0 + P_y \) record: (2.41)

2.42 \{True stop: two prime numbers \( P_1 \) and \( P_2 \), satisfying: \( P_1 + P_2 = 2n \). Any two prime numbers \( P_X \) and \( P_Y \) cannot satisfy: \( P_X + P_Y = 2n + 2 \)\} record: (2.42)

2.5 \{[References cited [3]] The theorem of infinite number of primes: the n bit after each prime can always find another prime. For example, 3 is followed by 5 and 13 is followed by 17; There must be an adjacent prime \( p_i \) after the prime \( P \)\} record: (2.5)

2.6 \{Here we only discuss the following cases: prime number sequence and even number sequence
(2.5)) \( \Rightarrow \) Prime number sequence: 3, 5, 7, 11, 13, 17, 19, 23, ...
Even number sequence: 6, 8, 10, 12, 14, 16, 18, 20, ...
Explain (2.5 ) in today's words: the prime number in the prime number sequence discussed in this paper is adjacent and continuous, and the first number is 3. An even number in an even number sequence is contiguous and the first number is 6.\} record: (2.6)

2.7 \{Remember: all the primes I'll talk about below refer to odd primes (excluding 2).
Prime symbol \( P \), different primes use \( P_1, P_2, P_3,..., P_x \)\} record: (2.7)

3 Text: Logical discussion (argument) and results

3.1 \{Goldbach conjecture^[1]: \( 3 \leq \forall n \in N, \quad 2n = p_1 + p_2 \). set up \( \Delta_1: p_x \geq p_y \)\}
record: (3.1)

3.2  \{  Theorem: the continuity of prime numbers leads to the continuity of even numbers. 

In mathematical language:

Known: \{3, 5, 7, 11, 13, …, p_2, p_1, p_0\} ∈ (prime). The next neighbor of p_1 is p_0,
3<5<7<11<13<… p_2<p_1<p_0,
\{ 6, 8, 10, 12, 14, 16, …., 2n\} ∈ (continuous even number).
If: \{3, 5, 7, 11, 13, …, p_2, p_1\} ⇒ \{ 6, 8, 10, 12, 14, 16, …, 2n\}.
inevitable: \{3, 5, 7, 11, 13, …, p_2, p_1, p_0\} ⇒ \{ 6, 8, 10, 12, 14, 16, …, 2n, 2(n+1)\}. record: (3.2)

3.2.1 prove:
Humans use computers to calculate a finite number of even numbers: \{6, 8, 10, 12, 14, ..., 2n\} every even number satisfies (3.1).
The computer process is finite \{6, 8, 10, 12, 14, ..., 2n\}.
It is not logically proved that any even number greater than 4 satisfies (3.1).
( (2.5)+(2.6) ) Take odd prime sequence: 3, 5, 7, 11, 13, 17, 19, 23, ...
Take the minimum prime number 3 from the front of the prime sequence,

A_1: \{(2.1)+(2.4)+\{3\}\} ⇒
\{3+3=6\} It is recorded as A_1
⇒ 6
According to the rule, 3 can only get \{3+3=6\}
Nonexistence: 5+p=6
【 Because 1 in 5+1=6 is not defined as a prime number. If 1 is defined as a prime number, this paper will come to the same conclusion 】

Note: 5∉\{3\}.
Prime number 3, limit is used according to (2.4), cannot be: 6⇒8.
\{(2.1)+(2.4)+\{3\}\} ⇒ : Quoting prime number 3 can only get even number 6.
A pseudo stop occurred (2.41).
If you want to: 6⇒8, you must add an adjacent prime number 5.
∴ \{3,5\}
⇒ 3⇒5

7
$A_2: \{ (2.1) + (2.4) + \{3,5\}\} \Rightarrow
3 + 3 = 6
3 + 5 = 8
5 + 5 = 3 + 7 = 10 \quad \therefore (2.4) \Rightarrow \{ (5 + 5), (3 + 7)\} \in 10.
7 + 5 = 12
7 + 7 = 11 + 3 = 14. \quad \therefore (2.4) \Rightarrow \{ (7 + 7), (3 + 11)\} \in 14.
11 + 5 = 13 + 3 = 16 \quad \therefore (2.4) \Rightarrow \{ (11 + 5), (13 + 3)\} \in 16.
11 + 7 = 13 + 5 = 18.
13 + 7 = 17 + 3 = 20. \quad \text{There is a new prime number 17 in continuity.}

Note: \{ (13 + 7), (17 + 3)\} \in 20. \text{ even numbers } \Rightarrow \{ 6, 10, 12, 14, 16, 18, 20 \}.

Prime numbers are continuous, and there is a new prime number 17.

$3 \rightarrow 5 \rightarrow 7 \rightarrow 11 \rightarrow 13 \rightarrow 17.$
even numbers \Rightarrow \{ 6, 8 \rightarrow 10 \rightarrow 12 \rightarrow 14 \rightarrow 16 \rightarrow 18 \rightarrow 20 \}.$

Wonderful continuity:
$\{ \{3, 5\} \rightarrow \{ 6, 8, 10\} \}.$
$(10) \rightarrow (10 = 3 + 7) \rightarrow 7 \rightarrow \{3, 5, 7\}.$

$\{ 3, 5, 7 \} \rightarrow \{ 6, 8, 10, 12, 14\}.$
$(14) \rightarrow (14 = 3 + 11) \rightarrow 11 \rightarrow \{3, 5, 7, 11\}.$

$\{ 3, 5, 7, 11 \} \rightarrow \{ 6, 8, 10, 12, 14, 16\}.$
$(16) \rightarrow (16 = 3 + 13) \rightarrow 13 \rightarrow \{3, 5, 7, 11, 13\}.$

$\{ 3, 5, 7, 11, 13 \} \rightarrow \{ 6, 8, 10, 12, 14, 16, 18, 20\}.$
$(20) \rightarrow (20 = 3 + 17) \rightarrow 17 \rightarrow \{3, 5, 7, 11, 13, 17\}.$

$\{ 3, 5, 7, 11, 13, 17 \} \rightarrow \{ 6, 8, 10, 12, 14, 16, 18, 20, 22\}.$
$(22) \rightarrow (22 = 3 + 19) \rightarrow 19 \rightarrow \{3, 5, 7, 11, 13, 17, 19\}.$

$\{ 3, 5, 7, 11, 13, 17, 19 \} \rightarrow \{ 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26\}.$
$(26) \rightarrow (26 = 3 + 23) \rightarrow 23 \rightarrow \{3, 5, 7, 11, 13, 17, 19, 23\}.$

Wonderful continuity is obtained: prime continuity, resulting in a new even continuity, and a new even number results in a new prime continuity.
According to the rule (2.4) and the existing computer capabilities, the prime number 23 should be continuous to the subsequent prime number.

According to the rule (2.4) and the existing computer capacity, the even number 26 should be continuous to the following even number, A2 has not stopped at this time.

Note the key point:
A1 pseudo stop, increase the adjacent prime number 5 to have A2.
From \( A_1 \rightarrow A_2 \rightarrow \) is it always infinite? Or will it stop?

Here's the wonderful thing:

(analysis I):
Always Unlimited: \( A_1 \rightarrow A_2 \rightarrow \ldots \)

There are: \((2.5)+(2.6) \Rightarrow \{3, 5, 7, 11, 13, 17, 19, 23, \ldots\}

Get: \( 6, 8, 10, 12, 14, 16, 20, 22, \ldots \)

Conclusion: (3.2) (QED).

\( (2.2) \Rightarrow \) Stop at \( A_n \), cannot continue.

(analysis II): Stop at \( A_n \), not to be continued.

Stop at \( A_n \): \( A_1 \rightarrow A_2 \rightarrow \ldots \rightarrow A_n \)

\( \kappa \)-line with continuous Prime: \( 3, 5, 7, 11, 13, 17, 19, 23, \ldots, p_2, p_1 \)

Get: \( 6, 8, 10, 12, 14, 16, 20, 22, \ldots, 2(n-1), 2n \)

Terminate at \( A_n \) to obtain:

\( \left\{ \left\{ (2.1)+(2.4)+\{3,5,7,11,\ldots,p_2,p_1\} \Rightarrow \{6, 8, 10, 12, \ldots, 2(n-1), 2n\} \right\} \right\} \) record: (3.3)

Terminate at \( A_n \) to obtain:

\( \left\{ \left\{ (2.1)+(2.4)+\{3,5,7,11,\ldots,p_2,p_1\} \neq \{2n+1\} \Rightarrow \{2(n+1)\} \not\in A_n \right\} \right\} \) record: (3.4)

Let: prime \( p \) satisfy: \( p \notin \{3,5,7,11,\ldots,p_2,p_1\} \), (3.3),(3.4).

\( \therefore \left\{ p_1 < p, (p+\forall p) \notin \{6, 8, 10, 12, \ldots, 2(n-1), 2n\},(p+\forall p) \not\in A_n \right\} \) (1)
Take the prime number that is greater than \( p_1 \) and adjacent to \( p_1 \) as \( p_0 \).

\[ \therefore \quad (1) \Rightarrow \{ p_0 + 3 \neq 2n \quad , \quad p_0 + 3 < 2n \} \]

\[ \therefore \quad p_0 + 3 > 2n \]

\[ \therefore \quad p_0 + 2 \geq 2n \quad \therefore \quad (\text{odd}) \neq (\text{even}) \]

\[ \therefore \quad p_0 + 2 > 2n \quad \Rightarrow \quad p_0 + 1 \geq 2n \quad \text{Record as} \ (W) \]

Starting from (Analysis II)

The principle of mathematical complete induction:

it is correct in the front, until \( A_n \).

Take the continuous prime number \((3,5,7,11,\ldots,p_2,p_1)\) from small to large.

\[ A_n : \quad \{(2.1) + (2.4) + \{ 3,5,7,11,\ldots,p_2,p_1 \} \} \Rightarrow \]

\[ \{ 3+3=6 \} \]

\[ 5+3=8 \]

\[ 7+3=5+5=10. \text{ set up: } (7+3=5+5) \quad \text{sequence: } 7>5 \]

\[ 7+5=12 \]

\[ 11+3=7+7=14. \quad \text{ set up } \Delta_2 : (11+3=7+7) \quad \text{sequence: } 11>7 \]

\[ 13+3=11+5=16. \quad \text{ set up } \Delta_2 : (13+3=11+5) \quad \text{sequence: } 13>11 \]

\[ 13+5=11+7=18. \quad \text{ set up } \Delta_2 : (13+5=11+7) \quad \text{sequence: } 13>11 \]

\[ 17+3=13+7=20. \quad \text{ set up } \Delta_2 : (17+3=13+7) \quad \text{sequence: } 17>13 \]

\[ 19+5=17+11=11+11=22. \quad \text{ set up } \Delta_2 : (19+5=17+11) \quad \text{sequence: } 19>17>11 \]

\[ 19+5=17+7=13+11=24. \quad \text{ set up } \Delta_2 : (19+5=17+11) \quad \text{sequence: } 19>17>13 \]

\[ \ldots \ldots \ldots \ldots \]

\[ p_{c_1} + 2 + p_{c_2} = p_{c_3} + 2 + p_{c_4} = \ldots = 2(n+1) \]

\[ p_{b_1} + 2 + p_{b_2} = p_{b_3} + 2 + p_{b_4} = \ldots = 2(n+1) \]

\[ p_{a_1} + 2 + p_{a_2} = p_{a_3} + 2 + p_{a_4} = \ldots = 2(n+1) \]

It is recorded as: \( A_n \)

\[ \Rightarrow : 6,8,10,12,14,16,18, \ldots , 2(n-1),2n. \]

In \( A_n \), it is specified that: \( p_{a_1} \geq p_{a_2} \)

In \( A_n \) it is specified that: \( p_{a_1} > p_{a_3} \) 【Reason: \( p_{a_1} + p_{a_2} = 2n \) must exist. \( p_{a_3} + p_{a_4} = 2n \), not necessarily. If \( p_{a_3} + p_{a_4} = 2n \), exists \( p_{a_1} \) and \( p_{a_3} \) if one of them is big, put the big one in the first place according to the regulations.

If: \( p_{a_1} = p_{a_3} \Rightarrow (p_{a_3} + p_{a_4} = 2n) \quad \subseteq (p_{a_3} + p_{a_4} = 2n) \)

(2.4) \( \Rightarrow p_{a_3} + p_{a_4} = 2n \) is deleted】

\[ \therefore p_{a_1} > p_{a_3} \]
A_n is simplified as B_n.

\[
\begin{align*}
3+3 &= 6 \\
5+3 &= 8 \\
7+3 &= 5+5 = 10. \\
7+5 &= 12 \\
11+3 &= 7+7 = 14. \\
13+3 &= 11+5 = 16. \\
13+5 &= 11+7 = 18. \\
17+3 &= 13+7 = 20. \\
19+3 &= 17+5 = 22. \\
19+5 &= 17+7 = 24.
\end{align*}
\]

.................

\[
\begin{align*}
p_{c1}+2+p_{c2} &= p_{c3}+2+p_{c4} = \ldots = 2(n+1) \\
p_{b1}+2+p_{b2} &= p_{b3}+2+p_{b4} = \ldots = 2(n+1) \\
p_{a1}+2+p_{a2} &= p_{a3}+2+p_{a4} = \ldots = 2(n+1)\end{align*}
\]

It is recorded as: B_n

Change B_n to C_n.

\[
\begin{align*}
\{ & \text{ Level 2(n-2): } 3+2(n-2)+3 = 2(n+1) \\
& \text{ Level 2(n-3): } 5+2(n-3)+3 = 2(n+1) \\
& \text{ Level 2(n-4): } 7+2(n-4)+3 = 5+2(n-4)+5 = 2(n+1) \\
& \text{ Level 2(n-5): } 7+2(n-5)+5 = 2(n+1) \\
& \text{ Level 2(n-6): } 11+2(n-6)+3 = 7+2(n-6)+7 = 2(n+1) \\
& \text{ Level 2(n-7): } 13+2(n-7)+3 = 11+2(n-7)+5 = 2(n+1) \\
& \text{ Level 2(n-8): } 13+2(n-8)+5 = 11+2(n-8)+7 = 2(n+1) \\
& \text{ Level 2(n-9): } 17+2(n-9)+3 = 13+2(n-9)+7 = 2(n+1) \\
& \text{ Level 2(n-10): } 19+2(n-10)+3 = 17+2(n-10)+5 = 11+2(n-10)+11 = 2(n+1) \\
& \text{ Level 2(n-11): } 19+2(n-11)+5 = 17+2(n-11)+7 = 13+2(n-11)+11 = 2(n+1)
\end{align*}
\]

.................

\[
\begin{align*}
p_{c1}+2+p_{c2} &= p_{c3}+2+p_{c4} = \ldots = 2(n+1) \\
p_{b1}+2+p_{b2} &= p_{b3}+2+p_{b4} = \ldots = 2(n+1) \\
p_{a1}+2+p_{a2} &= p_{a3}+2+p_{a4} = \ldots = 2(n+1)\end{align*}
\]

It is recorded as: C_n

【friendly note: C_n is Goldbach's conjecture channel. The branches of this channel are: Level 2, level 4, level 6,... Level 2 (n-3), level 2 (n-2)】

"Line β " in C_n: 2→4→6→8→.....→2(n-5)→2(n-4)→2(n-3)→2(n-2)

In C_n. (Level 2): \{p_{a1}, p_{a2}, p_{a3}, p_{a4}, ..., p_{an}\}, any element is modeled as p_a, and each prime is abbreviated as p_a.
In C_n. (Level 4): \{p_{b1}, p_{b2}, p_{b3}, p_{b4}, ..., p_{bn}\}, any element is modeled as p_b, and each prime is abbreviated as p_b.
The same analogy follows (at each level).

**Important note:** in C_n, I didn't specify p_{a1} > p_{b1}, I didn't specify their size.
3.2.1.1 Theorem (ω₁):

\{p₁ and p₀ are adjacent prime numbers. \quad p₀ > p₁ \} \Rightarrow p₀ > 2p₁.

Proof:

Assumptions: \quad p₀ > 2p₁.

\Rightarrow : p₀ > 2p₁ > p₁.

(2.3) + \{p₀ > 2p₁ > p₁\} \Rightarrow p₀ > 2p₁ > p₁.

\Rightarrow \{p₀ > p₁\} \text{ contradiction. } \therefore (p₁ and p₀ are adjacent prime numbers.)

\therefore p₀ > 2p₁.

Theorem (ω₁) (QED).

3.2.1.2 Theorem (ω₂):

Aₐ, Bₐ, Cₐ, If : \{2n+2 = pₓ+pᵧ. set up Δ₁: pₓ ≡ pᵧ\}

There must be: pₓ = p₀

Proof:

If: \quad pₓ + pᵧ = 2(n+1) \quad (2)

(w)+(2): \quad p₀ + 3 ≥ pₓ + pᵧ \quad (3)

\begin{align*}
\text{(w): } p₀ + 1 & ≥ 2n \Rightarrow p₀ + 1 + 2 ≥ 2n + 2 = pₓ + pᵧ \Rightarrow p₀ + 3 ≥ pₓ + pᵧ.
\end{align*}

\therefore (the smallest prime in \ k \ is 3)

\therefore pᵧ ≥ 3

\therefore (3) \Rightarrow p₀ ≥ pₓ \quad (4)

\begin{align*}
\therefore \{3.4\} & \Rightarrow \{(2.4) + \{3,5,7,11, \ldots , p₂, p₁\} \not\subseteq 2(n+1) = p₁ + pₓ\} \quad (5)
\end{align*}

\begin{align*}
\therefore \{1\} & + (5) \Rightarrow pₓ \in \{3,5,7,11, \ldots , p₂, p₁\} \Rightarrow pₓ > p₁ \quad (6)
\end{align*}

\begin{align*}
\text{reason: Hypothesis: } pₓ \in \{3,5,7,11, \ldots , p₂, p₁\}
\therefore pₓ ≥ pᵧ \Rightarrow \{pₓ, pᵧ\} \in \{3,5,7,11, \ldots , p₂, p₁\}
\quad \{3,5,7,11, \ldots , p₂, p₁\} \Rightarrow pₓ + pᵧ = 2(n+1) \quad \text{Contradiction with (5).}
\therefore pₓ \in \{3,5,7,11, \ldots , p₂, p₁\} \Rightarrow pₓ > p₁
\end{align*}

\{4\} + (6) \Rightarrow p₀ ≥ pₓ > p₁ \quad (7)

Because p₀ > p₁, and the prime number: p₀ and p₁ adjacent.

\{p₀ and p₁ adjacent. + (7) \} \Rightarrow \therefore pₓ = p₀

(ω₂) (QED).
3.2.1.3 Theorem(ω₃):

Known: \{ A_n, B_n, C_n, (2.2), (2.4), p₁ and p₀ are adjacent prime numbers, p₀ > p₁, \}

β line: 2 → 4 → 6 → 8 → \ldots → 2(n-6) → 2(n-5) → 2(n-4) → 2(n-3) → 2(n-2)

κ line: 3 → 5 → 7 → 11 → 13 → 17 → 19 → \ldots → p₂ → p₁

(2.2) Extreme law: Not allowed: \(2n+2=p_x+p_y\) \{ There must be: \(p₀ - p₁ > 2(n-2)\)

Proof:

\(p₁\) and \(p₀\) are adjacent prime numbers, \(p₀ > p₁\),

\(\because\) there is no prime number between \(p₁\) and \(p₀\) \(\because\) \(p₁\) takes precedence over other prime numbers and approaches \(p₀\).

Application

If: \(p₀-p₁=2\), There must be: \(p₁ = p₄\)

\(\because\) there is no odd number between \(p₀\) and \(p₄\), \(\because\) \(p₀ > p₁ ≥ p₄\).

If: \(p₁ > p₄\) There must be: \(p₀ > p₁ > p₄ \rightarrow p₁\) is even \rightarrow contradictory \(\therefore\) \(p₁ = p₄\)

If: \(p₀-p₄=4\), \(p₀-2₄\) \(\neq 2\). There must be: \(p₁ = p₄\)

\(\because\) The integer between \(p₀\) and \(p₄\) has only an odd number \(t\). \(\because\) \(p₀-2 = p₁ \rightarrow p₁ = t\)

\(\therefore\) \(p₀ > p₁ ≥ p₄\), If: \(p₁ ≠ p₄\) \(\rightarrow p₀ > p₁ > p₄ \rightarrow p₁\) is even \rightarrow contradictory \(\therefore\) \(p₁ = p₄\)

If: \(p₀-p₄=6\), \(p₀-2₄\) \(\neq 2\), \(p₀-1₄\) \(\neq 4\). There must be: \(p₁ = p₄\)

\(\because\) The integer between \(p₀\) and \(p₄\) has only two odd numbers \(t₄\).

\(\therefore\) \(p₀ > p₁ ≥ p₄\), If: \(p₁ ≠ p₄\) \(\rightarrow p₀ > p₁ > p₄ \rightarrow p₁\) is even \rightarrow contradictory \(\therefore\) \(p₁ = p₄\)

The same logic is extended (omitted). \(\}

Record as \((x)\)

\(\therefore\) Extreme law (2.2): not allowed: \(2n+2=pₓ+pₚ\)

\(\therefore\) \(2n+2 ≠ pₓ+pₚ\)

Under what conditions does \((2n+2=pₓ+pₚ)\) not exist?

Only if we find the condition that \(2n+2=pₓ+pₚ\) holds,

To get: \(2n+2 ≠ pₓ+pₚ\)

What are the conditions for the establishment of \((2n+2=pₓ+pₚ)\)?

If: \(2n+2=pₓ+pₚ\) holds.

(ω₂)+(\(2n+2=pₓ+pₚ\) \(\Rightarrow\) \(2n+2=p₀+pₚ\))

Get: \(pₓ = p₀\)

What is the value of prime \(pₚ\)?

\(\because\) \(2p₁ ≥ 2n \Rightarrow 2p₁+2 ≥ 2n+2\)

\(\therefore\) \(p₀ > p₁ \Rightarrow p₀ ≥ p₁+1\) \(\therefore\) (odd) \(\neq\) (even)
\[
\therefore p_0 > p_1 + 1 \implies 2p_0 > 2p_1 + 2 \\
\therefore (2p_1 + 2 < 2n+2, (2p_0 > 2p_1 + 2)) \therefore 2p_0 > 2n+2 \\
\therefore (2n+2 = p_0 + p_y, (2p_0 > 2n+2)) \therefore p_0 > p_y \\
\therefore p_y \in \{3, 5, 7, 11, 13, 17, 19, \ldots, p_2, p_1\} \\
\therefore \{3, 5, 7, 11, 13, 17, 19, \ldots, p_2, p_1\} + (2.4) \implies C_n \\
\therefore \{\text{Level 2}, \text{level 4, level 6, ..., Level 2 (n-3), level 2 (n-2)}\} \in C_n \\
\therefore \{3, 5, 7, 11, 13, 17, 19, \ldots, p_2, p_1\} \in \{\text{Level 2, level 4, level 6, ..., Level 2 (n-3), level 2 (n-2)}\} \\
\therefore p_y \in \{\text{Level 2, level 4, level 6, ..., Level 2 (n-3), level 2 (n-2)}\} \\
\]

If: \[p_y \in \{\text{Level 2}\}\]
\[
\therefore \{p_y \geq p_1\} \implies (p_y = p_{ai}) \implies 2n+2 = p_0 + p_{ai} \\
\therefore \text{Level 2:} \ p_{ai} \\
\therefore \text{Level 2:} (p_{ai} + 2 + p_{ai} = 2(n+1)) \in \{p_{ai} + 2 + p_{ai} = 2(n+1)\} \\
\therefore (p_{ai} + 2 = p_0 + p_{ai} + (p_{ai} + 2 + p_{ai} = 2(n+1))) \implies p_{ai} + 2 = p_0 \\
\therefore (p_{ai} + 2 = p_0) \implies (p_{ai} + 2 = p_0) \implies (p_0 - p_1 = 2) \\
\therefore \{2n+2 = p_x + p_y\} \implies (p_0 - p_1 = 2) \quad \text{Record as (i)} \\
\]

If: \[\text{Level 2} \quad p_x + 2 = p\]
\[
(p_x + 2 = p) \implies ((\text{Level 2}) \implies p + p_{ai} = 2n+2 \implies (p_x + p_y = 2n+2) \\
\therefore (p_x + 2 = p_0) \implies p_{ai} + 2 = p_0 \\
\therefore (p_x + 2 = p_0) \implies p_{ai} + 2 = p_0 \\
\therefore (p_x + 2 = p_0) \implies (p_x + p_y = 2n+2) \quad \text{Record as (ii)} \\
\]

(i)+(ii) Get: \[/p_x + p_y = 2n+2\] \iff \[/p_0 - p_1 = 2\] \quad \text{Record as (j)}

(j) The formula proves that the condition of \[/2n+2 = p_x + p_y\] in \text{Level 2} is: \[/p_0 - p_1 = 2\]
(2.2) Extreme laws do not allow: \[/2n+2 = p_x + p_y \implies 2n+2 \neq p_x + p_y\]
\[
\therefore \{j\} + \{2n+2 \neq p_x + p_y\} \implies p_0 - p_1 \neq 2 \\
\]

If: \[p_y \in \{\text{Level 4}\}\]
\[
\therefore \{p_y \geq p_1\} \implies (p_y = p_{bi}) \implies 2n+2 = p_0 + p_{bi} \\
\therefore \text{Level 4:} \ p_{bi} \\
\therefore \text{Level 4:} (p_{bi} + 4 + p_{bi} = 2(n+1)) \in \{p_{bi} + 4 + p_{bi} = 2(n+1)\} \\
\therefore (p_{bi} + 4 = p_0 + p_{bi} + (p_{bi} + 4 + p_{bi} = 2(n+1))) \implies p_{bi} + 4 = p_0 \\
\therefore (p_{bi} + 4 = p_0) \implies p_{bi} = p_1 \\
\therefore (p_{bi} + 4 = p_0) \implies (p_{bi} + 4 = p_0) \implies (p_0 - p_1 = 4) \\
\therefore \{2n+2 = p_x + p_y\} \implies (p_0 - p_1 = 2) \\
\]
If: Level 4 \( p_0 + 4 = p \),

\((p_0 + 4 = p) \Rightarrow (\text{Level 4}) \Rightarrow p + p_0 = 2n + 2 \Rightarrow (p + p_0 = 2n + 2) \)

\((\omega_3)(p + p_0 = 2n + 2) \Rightarrow p = p_0 \)
\[ \therefore (p_0 + 4 = p) \Rightarrow p_0 + 4 = p_0 \]

\((x + (\omega_3)(p_0 + 4 = p_0) \Rightarrow p_1 + 4 = p_0 \)
\[ \therefore (p_0 + 4 = p) \Rightarrow (p_0 + p_0 = 2n + 2) \]

The same logic leads to: \{ (p + p_0 = 2n + 2) \leftrightarrow (p_0 + p_0 = 4) \}

Record as \((\omega_3)\)

\[(jj)\] The formula proves that the condition of \((2n + 2 = p + p_0) \) in Level 4 is: \( p_0 - p_1 = 4 \)

(2.2) Extreme laws do not allow: \( 2n + 2 = p_0 + p_1 \Rightarrow 2n + 2 \neq p_0 + p_1 \)
\[ \therefore (jj) \Rightarrow (2n + 2 \neq p + p_0) \Rightarrow p_0 - p_1 = 4 \]

If: \( p \in \{\text{Level 6}\} \)
The same logic leads to: \{ \( 2n + 2 \neq p_0 + p_1 \) \} \( \Rightarrow p_0 - p_1 \neq 6 \)

---

...... Recursive derivation \( \rightarrow \)

\( \beta \) line: \( 2 \rightarrow 4 \rightarrow 6 \rightarrow \ldots \rightarrow 2(n-6) \rightarrow 2(n-5) \rightarrow 2(n-4) \rightarrow 2(n-3) \rightarrow 2(n-2) \)

\( C_n \): (Level 2 (n-2)) also follows the same principle: \( p_0 - p_1 \neq 2(n-2) \)

\{ \( p_0 > p_1 \) \\
\( p_0 - p_1 \neq 2 \) \\
\( p_0 - p_1 \neq 4 \) \\
\( p_0 - p_1 \neq 6 \) \\
\( p_0 - p_1 \neq 8 \) \\
... \\
\( p_0 - p_1 \neq 2(n-3) \) \\
\( p_0 - p_1 \neq 2(n-2) \} \Rightarrow p_0 - p_1 > 2(n-2) \)

Theorem(\( \omega_3 \)) \((\text{QED})\).

【Friendly tip: Goldbach's conjecture ball, kick into each branch of Goldbach's conjecture \( C_n \), and the ball is not allowed to encounter Goldbach's conjecture conclusion in each path. Then we get: \( p_0 - p_1 > 2(n-2) \).】

3.2.1.4 Theorem(\( \omega_4 \)): \( p_0 - p_1 > 2(n-2) \) violates "Bertrand Chebyshev theorem".

Proof:
\[(\omega_3) \Rightarrow p_0 - p_1 > 2(n-2) \Rightarrow p_0 - p_1 > 2n - 4 \Rightarrow p_1 + p_1 - 4 \]

【∵ \( 2n \geq p_1 + p_1 \)】
\( p_0 > (2p_1 + p_i - 4) \quad \therefore \quad p_0 > (2p_1 + p_i - 3) \)
\( \therefore \quad \text{(the smallest prime in } \kappa \text{ is } 3) \Rightarrow p_i > 3 \quad \therefore \quad (p_0 > 2p_1 + p_i - 3) \Rightarrow p_0 > 2p_1 \)
\( \therefore \quad p_0 > 2p_1 \)

**Theorem (\( \omega_1 \))** Get: \( p_0 > 2p_1 \) violates the "Bertrand Chebyshev theorem".
(\( \omega_4 \)) (QED).

### 3.2.1.5 Summary: Causes of contradictions
It is proved that it is wrong to quote "extreme law(2.2)" in this process. It leads to contradictions.
\( A_2 \rightarrow A_n \) can only be a pseudo stop, there can be no true stop.
As long as one of them does not quote the "extreme law(2.2)", You get:
\( p_x + p_y = 2(n+1) \Rightarrow p_0 + p_y = 2(n+1) \quad \quad \quad \text{【Theorem (\( \omega_2 \)) : } p_0 = p_x \quad \quad \quad \text{】} \)
(\( \omega_2 \)) \( \Rightarrow \) New (\( \kappa \) line): \( 3 \rightarrow 5 \rightarrow 7 \rightarrow 11 \rightarrow 13 \rightarrow 17 \rightarrow 19 \rightarrow \ldots \rightarrow p_1 \rightarrow p_0 \)

At this time, the complete proof \( A_n \) is followed by \( p_0 + p_y = 2(n+1) \)

(3.2) (QED).

(3.1) and (3.2) are equivalent: (3.2) (QED) \( \Rightarrow \) (3.1) (QED).

### 4 Conclusion

(3.1) and (3.2) are equivalent: (3.2) (QED) \( \Rightarrow \) (3.1) (QED).
Complete the mathematical complete induction:
\( \{ A_1 \quad (\kappa \text{ line:3) (3.1) (QED)}, \)
\( A_n \quad (\kappa \text{ line:3,5,7,...} p_1 \) (3.1) (QED),
\( A_{n+1} \quad (\kappa \text{ line:3,5,7,...} p_1,p_0 \) (3.1) (QED)\}.

"Authenticity stop" will not appear, so it is always infinite. \( \Rightarrow \) (3.1) (QED).
