Abstract

Muscle atrophy caused by long-term denervation leads to the loss of skeletal muscle mass and strength, resulting in a poor recovery of functional muscles and decreasing quality of life. Increasing differentially expressed microRNAs (DEMs) have been reported to be involved in the pathogenesis of denervated muscle atrophy. However, there is still insufficient evidence to explain the role of miRNAs and their target genes in skeletal muscle atrophy. Therefore, an integrative exploration of the miRNA-mRNA regulatory network in denervated muscle atrophy is necessary. A total of 21 (16 upregulated and 5 downregulated) DEMs were screened out in the GSE81914 dataset. Med1 was predicted and verified to be significantly upregulated, which may affect the process of denervated muscle atrophy by regulating mir-146b and mir-1949. 59 target genes were then predicted by submitting candidate DEMs to the miRNet database. GO and KEGG pathway enrichment analysis showed that target genes of DEMs were mainly enriched in the apoptotic process and PI3K/Akt signaling pathway. Through the PPI network construction, key modules and hub genes were obtained and potentially modulated by mir-29b, mir-132, and mir-133a. According to the qRT-PCR results, among the hub genes, Ctgf was significantly increased, which was consistent with the decreased mir-133a in denervated muscle atrophy. In the study, a potential miRNA-mRNA regulatory network was firstly constructed in denervated muscle atrophy. Two potential miRNA–mRNA pathways (miR-29b-COL1A1 and mir-133a-Ctgf) may provide new insight into the pathogenesis and treatment of denervated muscle atrophy.

Introduction

As an important effector organ of the peripheral nervous system, skeletal muscle is controlled and regulated by the peripheral nervous system. Generally, skeletal muscle adapts to slight external changes by secreting myokines and muscle metabolites, thus maintaining the homeostasis of the whole body[1, 2]. Once the peripheral nerve is transected, skeletal muscle is in a state of denervation, which will lead to the loss of signal transmission and material exchange with the peripheral nerve, resulting in a series of pathological changes related to muscular atrophy, including reduction of muscle fiber cross-sectional area and destruction of myofilaments and sarcomere. Skeletal muscle atrophy can lead to poor functional status, reduced quality of life, adverse impacts on life prognosis in patients, placing a heavy burden on families and society [3, 4]. However, there is no effective treatment strategy for denervated muscle atrophy in clinical practice. Therefore, it is urgent to study the molecular mechanism of muscle atrophy caused by peripheral nerve injury and explore new effective therapeutic targets.

MicroRNAs (miRNAs) are a class of highly conserved regulatory non-coding RNA molecules that consist of 18-25 nucleotides. They can negatively regulate gene expression at the posttranscriptional level by targeting degradation of messenger RNA (mRNA) or blocking protein translation[5, 6]. Studies have shown that dysregulated miRNAs are associated with the occurrence and development of a variety of diseases, including skeletal muscle development and muscle-related diseases. It was reported that many
mRNAs play a role in the biological and pathological process of muscle atrophy and regeneration, including miR-1, miR-23a, miR-21, miR-206, miR-322[7-9]. In addition, a growing number of studies have used cDNA microarrays to reveal the differential expression of many genes in atrophic muscles. These differentially expressed genes (DEGs) are mainly enriched in biological processes such as activating proteolytic pathways and inhibiting protein synthesis pathways[10]. Although many studies have been conducted on the expression and function of miRNA and mRNA in muscle atrophy, few studies have been performed to date on the role of the miRNA-mRNA regulatory network in denervated amyotrophic disease.

In this study, we screened differentially expressed microRNAs in gastrocnemius muscle after denervation injury compared with innervation by analyzing a miRNA array. Transcription factors (Tf) and target genes were obtained by predicting DEMs. Then a functional analysis of target genes was performed to clarify the biological process of muscle atrophy after denervation, and a DEM-hub gene network was conducted to discover key molecular mediators. In addition, the gastrocnemius muscle levels of hub genes were further verified by qQT-PCR. The purpose of this study was to furnish a novel perspective of miRNA–mRNA regulatory network in a model of denervated skeletal muscle atrophy to provide promising targets for denervated muscle atrophy treatment.

Results

Identification of DEMs in denervated muscle

Based on the analysis of the GSE81914 dataset, the DEMs list was obtained with the $|\log_{FC}| \geq 1$ and p-value < 0.05 as the threshold. Compared with innervated muscle samples, a total of 21 DEMs were detected in denervated muscle samples, including 16 upregulated DEMs and 5 downregulated DEMs. As shown in the volcano plot and cluster heatmap, we extracted a total of 21 DEMs from the expression matrix and obtained the distribution of upregulated and downregulated DEMs (Figure 1).

Prediction and Validation of Upstream Transcription Factors of DEMs

TransmiR v2.0 database was used to predict the potential upstream transcription factors of candidate DEMs. Of the 21 obtained DEMs submitted to TransmiR v2.0, 11 DEMs were predicted for 14 transcription factors (Figure 2a). One transcription factor can act on multiple miRNAs, and one miRNA can also be regulated by more than one transcription factor. For the downregulated DEM, mir-495, the transcription factors were Mlxipl, while for the upregulated DEMs, the transcription factors were Brd4, Hnf4a, Nfkb1, Rela, Gh1, Myod1, Camta1, Mecp2, Nkx2-2, Sox10, Ep300, and Nr3c1. Hnf4a acted on 6 DEMs such as mir-21, mir-132, mir-203, mir-326, mir-511, and mir-1949 simultaneously, while mir-132 was be regulated by 5 transcription factors (Nkx2-2, Mlxipl, Mecp2, Hnf4a, Camta1).
As shown in TF-miRNA regulatory network, Hnf4a, Nkx2-2, Mlxipl, and Med1 can simultaneously modulate more than one DEM, so we consider that they play a more important role in regulating denervated muscle atrophy. The qRT-PCR was applied to verify the expression trend of transcription factors in the two groups of muscle tissues. The results showed that compared with the sham group, Med1 was significantly up-regulated in the denervated muscles, while Hnf4a, Nkx2-2, and Mlxipl had no significant statistical difference between the two groups (Figure 2b).

Prediction and Construction miRNA-mRNA Regulatory Network

Among the candidate DEMs submitted to the miRNet database, a total of 59 target genes were predicted by 11 DEMs, of which 10 up-regulated DEMs predicted 55 target genes, and 1 down-regulated DEM predicted 5 target genes. For better visualization, we constructed a miRNA-mRNA regulatory network of DEMs and their target genes through Cytoscape software (Figure 3). In addition, the target genes predicted by each DEM are listed in Table 2.

GO and KEGG Analysis of Target Genes

To clarify the biological characteristics of target genes related to denervation-induced muscle atrophy, the DAVID was used to perform (Gene Ontology) GO analysis. The obtained results of the enriched GO terms were shown in figure 4. GO functional enrichment results include gene ontology biological process (BP), molecular function (MF), and cellular components (CC). Our results show that target genes mainly involve biological processes such as cellular response to amino acid stimulus, endodermal cell differentiation, positive regulation of apoptotic process, cell adhesion, cell-matrix adhesion, and cell migration. In the MF group, target genes were mainly enriched in extracellular matrix structural constituent, protein binding, fibronectin binding, protein kinase binding, identical protein binding, kinase binding, and glycoprotein binding. As shown in figure 4, target genes mainly involve the following cellular components, such as extracellular matrix, collagen trimer, basement membrane, cytosol, collagen type V trimer, cytoplasm, and extracellular space. These data indicated that in the denervation-induced muscle atrophy model, cells in the extracellular matrix, cytoplasm, and collagen trimer perform molecular functions such as protein binding, fibronectin binding, protein kinase binding, and extracellular matrix structural constituent, resulting in cell apoptosis, cell adhesion, and cell migration.

The (Kyoto Encyclopedia of Genes and Genomes) KEGG analysis was applied to explore enriched pathways of target genes. The enriched categories of KEGG pathways are shown in figure 4d. Results showed that the PI3K-Akt signaling pathway, Protein digestion and absorption, Focal adhesion, ECM-receptor interaction, and FoxO signaling pathway were enriched in denervated muscles, which provided molecular pathway mechanisms for studying denervated muscle atrophy.
Module Analysis and Hub Genes Expression Validation

The target genes of denervated gastrocnemius muscle were constructed to construct protein-protein interaction (PPI) networks by using the STRING database. A complex PPI network with 49 nodes and 175 edges was constructed after removing the isolated nodes. Two significant modules with high corresponding degrees, all of which have a score $\geq 5$, were screened by using MCODE in Cytoscape. GO and KEGG Enrichment analysis of module 1 and module 2 were displayed in figure 5. As shown in figure 5, the target genes of module 1 are regulated by mir-29b and mainly participate in biological processes such as cellular response to amino acid stimulus, endodermal cell differentiation, collagen fibril organization, collagen-activated tyrosine kinase receptor signaling pathway, and cell adhesion. The target genes module 2 are mainly enriched in the biological process of cell apoptosis. The most significant pathway in module 1 and module 2 was simultaneously enriched in the PI3K-Akt signaling pathway.

Among the 49 nodes, there are 18 central nodes were filtered with the criterion of degree score $\geq 10$. The 18 most crucial genes that shared high interaction were Col1a1, Mmp9, Col4a2, Col3a1, Pten, Col4a1, Mmp2, Col18a1, Col5a2, Vegfa, Ctgf, Foxo3, Col5a1, Col8a1, Col16a1, Col7a1, Col5a3 and Col12a1. Among them, 12 encode collagen-related genes, the target genes of mir-29b, are completely located in module 1 (Figure 5a). Therefore, we consider that the collagen-related genes regulated by mir-29b play an important role in muscle atrophy. Then, we used qRT-PCR to verify the expression trend of Mmp9, Pten, Mmp2, Vegfa, Ctgf, Foxo3. For upregulated DEMs, compared with innervated gastrocnemius muscle, the expression of Pten was not significantly changed, while Mmp9, Mmp2, FOXO3, and Vegfa expression was increased on the contrary. For downregulated DEMs, the expression of Ctgf was significantly increased. Therefore, mir-133a-Ctgf was identified as a potential regulatory pathway in denervated muscle.

Discussion

Due to the slow regeneration of injured axons, it usually takes at least 3 months to regenerate into the distal muscle tissue. After peripheral nerve injury, the target skeletal muscle may result in atrophy by losing its innervation[11, 12]. To improve functional motor recovery, it is necessary to explore the molecular mechanisms and pathological events underlying the progression of denervated muscle atrophy. Nowadays, the development of microarray data technology attracts more and more researchers to obtain a deeper understanding of the related mechanism of denervated skeletal muscle atrophy[13]. In this study, microRNA profiles dataset GSE81914 were extracted to identify DEMs between denervated muscle and innervated muscle. A total of 16 upregulated DEMs and 5 downregulated DEMs, which were significantly changed and regarded as candidate DEMs to be further analyzed. Among these DEMs such as mir-489, mir-381, mir-146b, mir-132, mir-203, mir-21 and mir-29b have been reported to play an important role in severe muscle-related diseases, such as cachexia-induced muscle atrophy,
immobilization-induced muscle atrophy, aging-induced muscle wasting models, myotonic dystrophy, spinal muscular atrophy and myopenia[14-18]. Notably, many miRNAs need to be further explored in the role of denervated muscle atrophy.

Transcription factors and microRNAs are two significant Gene regulatory factors at the transcriptional and post-transcriptional levels. They can mutually regulate one another and form a feed-forward loop to participate in biological processes[19, 20]. Therefore, understanding the crosstalk between the two regulators and their targets is a powerful way to reveal the complex molecular regulatory mechanisms in the denervation-induced muscle atrophy model. Mediator complex subunit 1 (Med1), as a component of the mediator coactivator complex, plays a broad role in nuclear receptor-mediated transcription[21]. In the year 2010, Robert et al. reported that muscle-specific Med1 knockout mice exhibited enhanced insulin sensitivity, improved glucose tolerance, increased mitochondrial density, and promoted the transition of muscles to slow fibers [22]. Overexpression of Med1 inhibits energy expenditure pathways in muscles may be a potential pathway for gastrocnemius atrophy after sciatic nerve transection. Following that, Med1-mir-1949 and Med1-mir-146b may participate in the pathogenesis of denervation-induced muscle atrophy and further experimental verification is needed. Myogenic differentiation 1 (Myod1), acts as a transcriptional activator, promotes the transcription of muscle-specific target genes. It regulates muscle cell differentiation by inducing cell cycle arrest, which is a prerequisite for the initiation of myogenesis. Myod1 has been reported significantly up-regulated early after sciatic nerve compression, indicating that it started to play a role in initial muscle atrophy[23]. RELA proto-oncogene (Rela), a component of the NF-kappa B complex, and nuclear factor kappa B subunit 1 (Nfkb1) jointly constitute a transcriptionally active NF-kappa B dimer, which participates in the expression of genes in the processes of immunity, inflammation, and apoptosis[24]. Nuclear factor Kappa B (NF-κB) has also been reported to be a prominent signaling molecule in the pathogenesis of skeletal muscle atrophy, and many muscular atrophy-related genes, including MuRF1, MyoD and cyclin D ubiquitin-binding enzyme (E2), are its target gene[25]. Previous data indicated that NF-κB signaling increased due to aging, and inhibition of p65 reversed muscle atrophy caused by elevated pro-inflammatory/catabolic cytokines [26, 27]. However, longitudinal studies investigating the role of NF-κB in denervation-induced muscle atrophy are limited. In general, these transcription factors also in turn support the importance of these candidate DEMs in the pathogenesis of denervation-induced muscle atrophy.

The GO analysis results showed that the target genes of DEMs in module1 are mainly enriched in biological processes such as collagen fibril organization and cell adhesion, while in module 2, they are mainly enriched in the apoptotic process. In previous studies, activation of apoptotic process in muscle in response to denervation has been amply documented in neuromuscular diseases such as peripheral nerve injury, peripheral neuropathy, and amyotrophic lateral sclerosis (ALS)[28]. A study conducted by Zhenbing Chen et al. showed that denervation drives skeletal muscle atrophy by inducing mitochondrial
dysfunction, mitochondrial autophagy, and apoptosis, indicating that inhibiting the apoptotic process is essential before denervated muscle atrophy [29]. Although the changes of collagen fibrous tissue in the process of denervation of muscular atrophy have not been described, Pillihp et al. has shown that inhibiting microRNA-29 expression promotes collagen expression, which is consistent with our results[30]. KEGG analysis results showed that the target genes of DEMs in the two modules are mainly enriched in the PI3K-Akt signaling pathway. Inactivation of the IGF-1-PI3K-AKT signal will result in increased protein degradation and decreased protein synthesis, and will prevent muscle atrophy by inhibiting the FOXO transcription factor. MiR-29 has been demonstrated to damage muscle progenitor cell proliferation and induce various types of muscle atrophy by targeting PI3K[18, 31]. In the present study, COL1A1, as a hub target gene of miR-29b, was significantly enriched in collagen fibril organization, extracellular matrix, protein digestion and absorption, and PI3K/Akt signaling pathway. Therefore, miR-29b may regulate the extracellular matrix structural constituent in denervated skeletal muscle by targeting COL1A1 via the PI3K/Akt signaling pathway.

All hub genes in the construction of the DEM-hub gene network were potentially targeted by mir-132, mir-29b, and mir-133a. Among the hub genes verified by qRT-PCR, only the expression of Ctgf can constitute a miRNA-mRNA regulatory pathway with mir-133a. MiR-133a, a molecular marker for muscle differentiation and atrophy, has become a key regulator of myogenic programs by targeting specific muscle target genes. As a myogenic miRNA, it is involved in the process of muscle remodeling in neuromuscular disorders such as ALS, SMA, and SBMA [32]. However, unlike its expression in other muscle diseases, it decreases in denervated muscles. The expression difference of mir-133a may be regarded as a molecular marker to further elucidate the difference between upper and lower motor neuron neuromuscular diseases. Cell communication network factor 2 (CCN2/CTGF) is well known as a central mediator of tissue remodeling and fibrosis, which can reverse the process of fibrosis by its inhibitory effect. According to reports, CCN2/CTGF levels increase rapidly after skeletal muscle denervation by activating the TGF-β signaling pathway[33]. Brandan et al have shown that reducing CCN2/CTGF is beneficial to skeletal muscle and promoting muscle regeneration by reducing fibrosis[34]. The role of mir-133a and Ctgf in the development and regeneration of muscle, and in agreement with the regulatory relationship in the results of this study, indicate that inhibiting the mir-133a-Ctgf pathway may improve denervated muscle atrophy.

Although this is the first analysis to explore the potential miRNA-mRNA regulatory network in denervated muscular atrophy by bioinformatics analysis and qRT-PCR experiments, some limitations of our study need to be considered in depth. Firstly, sufficient sample sizes of different species are needed to further improve the reliability of the analysis. Secondly, we only focused on miRNAs - mRNAs regulation relationship between denervated and innervated gastrocnemius muscle, however, some of these may vary
in different stages of denervated muscle atrophy need more attention. Thirdly, further molecular biological experiments in vivo and in vitro are required to verify the miRNA–mRNA interactions.

**Conclusion**

In summary, based on the GEO database and bioinformatics analysis, we firstly revealed the regulatory relationship between transcription factors and miRNA and constructed two potential miRNA–mRNA pathways (miR-29b - COL1A1, mir-133a - Ctgf) in denervated muscle atrophy. Our findings yield new mechanistic insights and molecular targets of effective treatments for denervated muscle atrophy.

**Materials And Methods**

**Animal Experiment**

The 10-week-old Sprague-Dawley rats with the weight of 200±20g were provided by the Laboratory Animal Center of the Academy of Military Medical Sciences and housed on a 24 hours day-night cycle under temperature 21–23 °C. All experimental procedures were following the guidelines of the National Institutes of Health in the Guide for the Care and Use of Laboratory Animals (NIH Publications No. 85-23, revised 1996). Experimental protocols were approved by the Ethics Committee of Tianjin Institute of Radiation Medicine (IRM-DWLL-2019039).

The animals were randomly divided into experimental group and sham group (n = 6 each group). For experimental groups, the rats were anesthetized with an intraperitoneal injection of pentobarbital before the sciatic nerve was exposed and cut off through an incision at the mid-thigh region of the hind limb. For a sham group, the rats were operated on a similar surgical procedure but only an incision without sciatic nerve transection. The rats were sacrificed by cervical decapitation to harvest gastrocnemius muscle at 5 days post-injury respectively.

**Microarray Analysis and DEMs Screening**

Downloaded from the GEO database, microRNA profiles dataset GSE81914 (Li et al. submitted data 2018) was obtained. GSE81914 is an experimental microarray dataset designed on skeletal muscle atrophy induced by denervation, which includes gastrocnemius muscle samples 5 days after denervation injury (n=4) and sham control (n=4). Its platform is GPL10558(Affymetrix Multispecies miRNA-3 Array). GEO2R ([http://www.ncbi.nlm.nih.gov/geo/geo2r/](http://www.ncbi.nlm.nih.gov/geo/geo2r/)), an R-based online tool to analyze GEO data[35], was applied to compare and screen DEMs between denervated muscle and innervated muscle. We considered P-value <0.05 and |logFC| ≥1 as the threshold value.
Prediction of Transcription Factors and Target Genes of DEMs

TransmiR is an online transcription factor (TF)-microRNA (miRNA) regulation database, which has detailed annotations and experimental validation on all TF-miRNA regulations. TransmiR v2.0 database was used to predict the potential upstream transcription factors of candidate DEMs[36]. MiRNet is an online tool designed to help elucidate comprehensive microRNA functional annotation, explore miRNAs and their potential targets, and create miRNA-target interaction networks. As a miRNA-centric network visual analytics platform, miRNet was applied to predict the potential downstream target genes of obtained DEMs[37].

Functional Enrichment Analysis

As a database with high data coverage for annotation, visualization, and integrated discovery, DAVID (https://david.ncifcrf.gov/) can provide characteristic gene term enrichment analysis for uploaded gene lists [38]. Gene ontology analysis is widely used to analyze and interpret genomic sequencing because it can annotate genes and gene products[39]. KEGG is a database resource, the desired environment for analyzing variable datasets, containing advanced functional information for understanding gene functions and biological pathways of the cell and the organism[40].

Screening and Analysis of Hub Genes from Integration of PPI Networks

By the Search Tool for the Retrieval of Interacting Genes (STRING), a database widely used to evaluate functional interactions between proteins, we constructed and analyzed the PPI network of target genes. Moreover, we set the comprehensive score> 0.4 as the threshold and removed all isolated nodes[41]. Cytoscape software was applied to further visualize and analyze the PPI network. To calculate the number of interconnections and filter highly connected genes, the PPI network was performed by CytoHubba[42]. The top 10 nodes of the PPI network degree score were regarded as hub genes.

qRT-PCR Validation

Total RNA extraction from denervated and innervated gastrocnemius muscle samples with TRIzol Reagent (Invitrogen, USA). Reverse transcriptional PCR was performed to synthesis complementary DNA (cDNA) by using HiFiScript gDNA Removal RT MasterMix (CWBIO, Beijing, China) following the protocol. The mRNA level was assessed using Universal SYBR Green qPCR Supermix (UE, China) following the instructions. LightCycler® 96 (Roche, China) was applied to conduct real-time PCR, and the relative expression of the candidate gene was calculated by the $2^{-\Delta\Delta Ct}$ method with the normalization to GAPDH. The sequences of primers are available in Table 1.
Statistical analysis

The results of different groups were represented by the mean ± s.e.m. The comparison of expression levels of denervated and innervated gastrocnemius muscle tissues was analyzed by unpaired, two-tailed Student's t-test. \( P<0.05 \) was considered to represent a statistically significant difference.
