Abstract

Background: Deep brain stimulation (DBS) targeting the subthalamic nucleus (STN) can be used to treat motor symptoms and dyskinesia in the advanced stages of Parkinson's disease (PD). High frequency stimulation (HFS) of the STN can lead to consistent, long-term improvement of PD symptoms. However, the effects of HFS on the axial symptoms of PD, specifically freezing of gait (FOG), can be limited or cause further impairment. While this can be alleviated via relatively low frequency stimulation (LFS) in select patients, LFS does not control all motor symptoms of PD. Recently, the National Engineering Laboratory for Neuromodulation reported preliminary findings regarding an efficient way to combine the advantages of HFS and LFS to form variable frequency stimulation (VFS). However, this novel therapeutic strategy has not been formally tested in a randomized trial. **Methods/Design:** We propose a multicenter, double blind clinical trial involving 12 study hospitals and an established DBS team. The participants will be divided into a VFS and a constant frequency stimulation (CFS) group. The primary outcome will be changes in Stand-Walk-Sit (SWS) task scores at three months of treatment in the "medication off" condition. Secondary outcome measures include specific item scores on the Freezing of Gait Questionnaire and quality of life. The aim of this trial is to investigate the efficacy and safety of VFS compared with CFS. **Discussion:** This is the first randomized controlled trial to comprehensively evaluate the effectiveness and safety of VFS of the STN in patients with advanced PD. VFS may represent a new option for clinical treatment of PD in the future. **Trial registration:** The present protocol is registered at ClinicalTrials.gov: NCT03053726.

Background

Deep brain stimulation (DBS) of the subthalamic nucleus (STN) is an established treatment for Parkinson's disease (PD). However, debilitating axial symptoms such as gait impairment, postural instability, postural abnormalities, dysphagia, and dysarthria are frequently observed in individuals with advanced PD [1]. Axial motor impairments can be highly debilitating, and are a common cause of disability in patients with PD. Freezing of gait (FOG) is a unique and disabling clinical phenomenon that typically occurs when initiating gait or when turning while walking. It is characterized by brief episodes in which the patient demonstrates an inability to step, or makes repeated use of extremely short steps [2]. The inability to start walking is a prominent feature in PD patients with FOG. However, once this so-called 'freezing' pattern is interrupted, patients often regain the ability to walk normally [3]. FOG has also been observed in patients with progressive supranuclear ophthalmoplegia, multiple system atrophy, corticobasal degeneration, and numerous other diseases [4]. Additional axial signs include postural instability and changes in postural alignment, such as camptocormia or Pisa syndrome. Dysphagia and speech disorders, especially dysarthria and stuttering, are equally disabling axial motor features. However, conventional DBS stimulation has limited therapeutic potential for treating these symptoms. Thus, these symptoms represent a public health issue for which a specific treatment is currently lacking.

High-frequency DBS of the STN (STN-HFS) mainly improves levodopa-sensitive PD symptoms. However, it is typically less effective in improving axial symptoms, such as FOG [5]. Previous studies have shown

that subthalamic stimulation with low frequency (STN-LFS) improves axial motor activity in some PD patients, but with short-term therapeutic efficacy. Thereafter, patients may present with increased tremor, rigidity, and bradykinesia, and the intensity of symptoms often outweighs the initial benefits of LFS therapy for FOG [6, 7]. Previously, we successfully used variable frequency stimulation (VFS) of the STN to treat FOG in PD patients [8]. Further, we recently conducted a study with 28 participants (under review) that revealed that, compared with HFS and LFS, VFS DBS improved FOG and appendicular motor symptoms in PD patients with sustained benefits for 12 months. Our pilot study suggested that VFS composed of both HFS and LFS was safe, and we did not observe any clinically relevant neuropsychiatric adverse effects. To the best of our knowledge, no controlled prospective studies have compared VFS with constant frequency stimulation (CFS) in patients with PD. To this end, we designed a prospective, controlled study investigating the outcome of VFS in patients with advanced PD.

Aims

The motives for this clinical study are twofold. First, we plan to evaluate the short-term effects of VFS and CFS on motor and axial symptoms in patients with advanced PD. Second, we hope to gain insight regarding whether VFS is more effective than CFS after 3 months of treatment, with a 6-month follow-up period. The study has a randomized double-blind design.

Methods

Trial design

The RESTEP Study (ClinicalTrials.gov ID: NCT03053726) is a double blind, randomized, multicenter trial designed to evaluate the safety and effectiveness of STN-VFS treatment in participants with advanced PD. According to the trial flow chart (Figure 1), participants with advanced PD who had previously undergone DBS will be screened based on strict inclusion and exclusion criteria. A total of five follow-up surveys will be scheduled as shown in Table 1. After recruitment, pulse generators previously implanted in all participants will be upgraded from those with a single mode (CFS only) to those that are capable of dual mode stimulation (CFS or VFS). Following this upgrade, participants will be randomly and equally divided into two groups, the CFS group and the VFS group. After 3 months of stimulation in the blinded conditions, all participants will receive VFS and follow-up assessments for 6 months. To make any amendments to the protocol (Protocol Number: PINS-VFS-1601; Date: 10/11/2016), approval will be sought from the Institutional Review Board of Tiantan hospital. The protocol design is based on the guidelines of the Consolidated Standards of Reporting Trials (CONSORT) and Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT), and the study results will also be reported according to these guidelines. Informed consent will be obtained from all participants in accordance with the policies of the board.

Trial population

The trial will be conducted in approximately 12 centers. These include Beijing Tiantan Hospital, the first affiliated hospital of Dalian medical university, Nanjing brain hospital, Tangdu Hospital (Fourth Military Medical University of Chinese PLA), Qilu Hospital, Peking union medical college hospital, Chinese PLA general hospital, the second people's hospital of Shenzhen, Changhai hospital of Shanghai, the general hospital of Shenyang military, Huashan hospital, Shao Yi-fu Hospital affiliated to Zhejiang University Medical College. Other hospitals will be invited to join the study according to interest, feasibility, and resources. The clinical investigators from each center will be responsible for screening eligible participants.

Patient population and recruitment

We intend to enroll a total of 106 participants aged over 18 years. The prospective cohort will comprise PD patients who have received STN-DBS treatment and have implanted impulse generators that are compatible with VFS (PINS Medical).

Inclusion criteria

1. Patients with idiopathic Parkinson's disease
2. Aged ≥ 18 years, both male and female
3. Patients who have already undergone DBS and currently have an implanted STN-DBS stimulator
4. A Mini-Mental State Examination (MMSE) score of ≥ 24
5. A Hoehn-Yahr (H-Y) score of ≥ 2.0 when undergoing CFS in a "medication off" state
6. A score of ≥ 1 on the 14-item Unified Parkinson's Disease Rating Scale II (UPDRS-II)
7. A score of ≥ 2 on the 15-item UPDRS-II
8. The ability to walk ≥ 10 meters independently when receiving CFS in a "medication off" state

Exclusion criteria

1. Pregnant women, breastfeeding mothers, or woman who are unable to take effective measures to prevent pregnancy
2. Presence of other diseases that can affect walking distance, such as joint disease in the lower body, spinal disease, neuropathy, or serious heart or lung disease
3. Serious health conditions such as tumor, liver or kidney disease, etc.
4. Epilepsy or other seizure disorders
5. Mental disorders or dementia
6. Inability to comprehend the experimental protocol or voluntarily provide informed consent
7. Lack of cooperation with follow-up requirements
8. Additional reasons for exclusion at the discretion of the clinical investigator

Recruitment of participants

Participants will be recruited via advertisements online and directly at the participating hospitals.

Interventions

Constant Frequency Stimulation (CFS)

To deliver CFS, electrical stimulation will be set to a constant frequency by the physician programming the stimulation frequency parameters, i.e., the pulse width and amplitude. The participants will receive STN-DBS with single frequency, single pulse width, and single amplitude stimulation.

Variable Frequency Stimulation (VFS)

The VFS parameters will be selected based on previous findings regarding the relationship between stimulation frequency and movement rhythm regulation in humans. The stimulation frequency will be set to alternate between high and low frequencies.

Concomitant interventions

Participants will be allowed to continue taking medications they had been on before the trial. Use of all drugs, if any, will be documented in the Case Report Form (CRF).

Randomization and blinding

Eligible participants will be randomly assigned to one of two groups (CFS group or VFS group) after completing the baseline measurements. A 1:1 assignment sequence (based on computer-generated random numbers) will be produced by The Peking University Clinical Research Institute. The computer-generated random numbers will be used to create the participant numbers and order lists, which will be placed in opaque sealed envelopes and sent to the research centers. The research clerk will keep copies of the order lists and participant numbers.

Throughout the study, with the exception of the study programmer, all participants and study staff (including investigators, trainers, and statisticians) will be blinded to the treatment allocation. Independent raters who have no therapeutic relationships with the participants and who are blind to the treatment conditions will conduct outcome assessments. The independent raters will be clinical neurologists who have received additional training on the use of the outcome assessments, had the opportunity to listen to conducted assessments, and received direct feedback regarding their assessments from supervisors. Further, the Data and Safety Monitoring Board will review a random selection of 20% of the recorded assessments. Loss of blinding may occur due to the magnitude of the therapeutic effect or any other subjective perception that indicates that VFS or CFS is delivered.

Trial outcomes

Primary clinical outcomes

The primary outcome will be Stand-Walk-Sit (SWS) task scores at 3 months compared with the baseline scores. The SWS test is a simple and quick functional mobility test that requires an individual to stand up, walk 5 m, turn, walk back, and sit down. The time taken to complete the test is strongly correlated with the level of functional mobility. This test will be videotaped and scored by two blinded neurologists.

Secondary clinical outcomes

As secondary outcomes, we will use the Freezing of Gait Questionnaire (FOGQ), Gait and Falls Questionnaire (GAFQ), and Parkinson's Disease Quality of Life questionnaire (PDQ-39), as well as total UPDRS and UPDRS III scores to assess PD symptom severity. These questionnaires assess physiological symptoms and emotional function in PD patients. Participants in both trial groups will be asked to complete these questionnaires at baseline and post-treatment, and the trial group will also be asked to complete the measures 3-months and 6-months post-treatment.

Withdrawal from the study

In case of endangerment of personal safety, lack of compliance, or withdrawal of informed consent, a patient will instantly be excluded from the study. Further, participants will be withdrawn from the study in the following conditions: (1) The patient's parents require withdrawal; (2) The patient develops heart failure, respiratory failure, or another serious disease.

Safety aspects

Adverse Events

An adverse event (AE) could include an abnormal laboratory finding, symptom, or disease temporally associated with the administration of an investigational product, regardless of whether it is related to that investigational product. In the present study, an unexpected AE is anything that is not identified in nature, severity, or frequency in the Investigator's Brochure. During routine assessments, the investigator will question the participants about the occurrence of AEs and record the information in the source documents and patient case report form (CRF).

Serious Adverse Events (SAEs)

- Death
- A life-threatening adverse experience
- Inpatient hospitalization or prolongation of existing hospitalization
- A persistent or significant disability/incapacity
- A congenital anomaly/birth defect

Other important medical events may also be considered SAEs when, based on appropriate medical judgment, they jeopardize the participant or require intervention to prevent one of the outcomes listed.

When AEs occur throughout the clinical trial, investigators may take necessary measures according to the condition of the participant. Based on the severity of the AE, the investigators may choose hospitalization, outpatient treatment, home visits, communication, or other follow-up methods.

Data and Safety Monitoring Board (DSMB)

The DSMB will review the safety, ethics, and outcomes of the study. It is independent from the sponsor and has no competing interests. DSMB members will monitor blinded assessment data for SAEs or potential harmful effects. A charter that will outline member responsibilities, procedures, and confidentiality will govern the DSMB. The DSMB will also review unblinded data at regular intervals during the follow-up period and will monitor neurological and functional differences between the two groups, as well as dropout and event rates.

Data quality and management

The participants will be randomly selected and any reasons for exclusion will be recorded in their medical records and reviewed by the trial monitor.

Data collection and monitoring

1. CRFs must be completed according to the schedule.
2. All SAEs that occur during the observation period must be reported to the medical expert overseeing the investigation, i.e., the medical director of Beijing PINS Medical Co., Ltd.
3. The investigators are responsible for all information collected about participants enrolled in this study.
4. The monitoring system will assure the quality of the assessments.
5. The data will be entered into a validated database.
6. The Data Management Group will be responsible for data processing, in accordance with procedural documentation. The database will be locked once quality assurance procedures have been completed.

Handling of Missing Data

All variables included in the CRF are mandatory.

Data auditing

This trial will be audited by the Research Ethics Committee and the China Food and Drug Administration.

Statistical considerations

Sample size

The sample size was calculated based on the primary outcome measure according to the results of our pilot study. Power was set at 80% and calculated based on two-sided 95% confidence intervals. In our pilot data, we detected a post-treatment difference in PD symptoms of at least 20% between the VFS and CFS groups of SWS scores. We assume that the placebo effect can account for about 10% of such differences. The sample size in each group was determined using a formula derived by Whitley et al. We assume that 10% of the trial participants will be lost to attrition. Thus, 53 participants need to be allocated to each treatment group to establish a difference among the treatments at a level of 5% with a power value of 90%.

Data analysis

All evaluations of effectiveness and safety will be conducted according to the intention-to-treat (ITT) principle. The final data will be analyzed using IBM SPSS 13.0 or higher (SPSS, Inc., Chicago, IL, USA) and SAS 9.4 or higher (SAS Institute Inc., Cary, NC, USA) software. A p-value < 0.05 will be considered statistically significant. Data will be analyzed with t-tests and χ^2 tests for continuous variables and categorical variables, respectively.

Confidentiality

When participating in research there is always a risk regarding the confidentiality of information. All information gathered in the present study will be stored in a secure database. All participants will provide written informed consent prior to being assessed for eligibility for inclusion in any part of the study. Every precaution will be taken to respect the privacy of participants in the conduct of the study. Information will be stored on a password-protected server with access that is limited to members of the study team. In the course of monitoring data quality and adherence to the study protocol, the monitors will refer to medical records at the participating hospitals. All individual and site information will be de-identified when reporting the data and results to protect the confidentiality of the participants.

Discussion

Axial and appendicular motor symptoms severely affect quality of life in PD patients. DBS is an effective well-established therapy for medication-refractory PD patients. High-frequency DBS is highly efficacious in ameliorating appendicular symptoms in PD patients, but less effective in improving axial symptoms, especially on a long-term basis [5]. New conceptions of DBS have focused on the use of LFS or combined STN/SNr-DBS for the treatment of axial symptoms in PD patients [6, 9, 10]. LFS may help improve postural control as well as gait, particularly in PD patients who do not develop gait-related disorders after HFS [11]. However, the beneficial effects of LFS on axial symptoms remain controversial [12]. Therefore, the development of novel approaches to managing both axial and appendicular motor symptoms in PD patients is critical. Based on these findings and our previously published case report [8], we hypothesize that PD patients with FOG might benefit from STN-VFS. This multicenter double-blind randomized clinical trial will enable us to evaluate the effect of a novel STN-VFS stimulation pattern on both axial and segmental symptoms of PD. This study was designed to evaluate the short-term effects and potential

side effects of VFS and CFS on axial symptoms in advanced PD. We hope to gain insight regarding whether VFS or CFS is more effective for treating axial symptoms of PD. This study has several strengths. First, group-assignment in the double-blinded phase was randomized. Second, we performed a power calculation for this study. At present, the total number of patients enrolled in the study is 106.

Trial Status

The trial is ongoing and is actively enrolling. The protocol version 1.1, PINS-VFS-1601, 11/10/2016. The trial will be ongoing from August 2017 to December 2019.

Declarations

Acknowledgements

We would like to thank the entire team of researchers, including the nurses and staff at all 12 hospitals, for their determination, professional skills, enthusiasm, and effort.

Funding

This study was supported by National Key Development Plan of China (Grants no. 2016YFC0105900) and National Natural Science Foundation of China (Grants no. 81701120). Funding 2016YFC0105900 is responsible for the study organization and conduct. Funding 81701120 is responsible for the study design, meeting and transportation.

Availability of data and material

Data from this randomized controlled study are unavailable at the time of publication. Individual participant data is available upon request.

Author contributions

Conception and design: FMJ, LML; Study coordination: FMJ, JGZ; Acquisition of legal authorization and datas: JGZ, ZHL, WGL, XLW, YML, YG, ZPL, XDC, XW, YQT, JJW, WL, XX, NL, WBZ; Drafting and writing of the manuscript: FMJ; Revision the approval of the final version of the manuscript: LML; All authors reviewed and approved the final version of the manuscript.

Ethics, consent, and participants

The study will be conducted according to the Good Clinical Practice Guidelines and the principles of the Declaration of Helsinki. Written informed consent will be obtained from each participant. The study protocol was approved by the Medical Ethics Committee Board of every center. Informed consent will be provided by all participants, including their consent regarding the publication of the results. Confidentiality will be ensured during all handling of the data. This study has been approved by Ethics Committee of Beijing Tian Hospital, Capital Medical University (number, QX2016-015-02).

Consent for publication

Not applicable.

Competing interests

The authors declared that they have no competing interests.
