Abstract

**Background:** Etiology of polycystic ovary syndrome (PCOS) is unclear. Recent reports indicated that gut microbiota regulates metabolism and plays a major role in the development of PCOS.

**Methods:** We used dihydrotestosterone (DHT) or letrozole (LET) to induce PCOS model rat. At the end of the experiment, ovarian morphology, hormonal and metabolic status were investigated in all rats. The molecular ecology of the fecal gut microbiota was analyzed by 16S rDNA high-throughput sequencing.

**Result:** Rats induced by letrozole exhibited endocrine and reproductive characteristics, such as hyperandrogenism, abnormal oestrus cycles or complete acyclic, polycystic ovaries, and obesity. DHT-induced rats were showed obesity, irregular oestrus cycles, polycystic ovaries, lower level of HDL-C and lower activity of SOD than controls. Our study found that DHT can reduce the microbial richness in rats. PCoA plots confirmed that DHT group was statistically significantly separated from C group and LET group. LEfSe analysis showed that the family of *Bacteroidales_S24_7_group*, and genus *Peptococcus* and *Turicibacter* may play vital roles in the health and function of control group. Genus of *Bifidobacteriales* and *Vibro* may play roles in the letrozole induced PCOS rats. And genus of *Lachnospiraceae_NK4A136_group*, *Ruminococcus_1*, *Ruminiclostridium*, *Treponema_2*, *Anaerotruncus*, *Acetatifactor* and *Anaeroplasma* may play vital roles in the intestine of DHT induced PCOS rats.

**Conclusion:** DHT affected the composition and diversity of gut microbial community, and leads to the gut dysbiosis. Letrozole may benefit to the gut microbiome in some aspects, but it also may have a trend of inhibiting the expression of some anti-inflammatory genera in intestinal tract.

Introduction

Polycystic ovary syndrome (PCOS) is a multifactorial, heterogeneous and complex genetic, endocrine and metabolic disease, which is characterized by hyperandrogenism, hyperinsulinemia, insulin resistance (IR) and chronic anovulation. [1-3]. Hyperandrogenism may play an important role in altering the gut microbiome in women with PCOS [4]. Some studies have reported that compared with healthy women, the overall bacterial species richness (α diversity) of the gut microbial community of PCOS women decreased, and several bacterial taxa changed [5,6]. Zhang et al. [7] confirmed that gut microbiome was involved in the development of IR and menstrual disorders in PCOS patients by affecting intestinal wall permeability. Some researchers believed that dysbiosis of gut microbiota can increase the production of ovarian androgen, and then interfere with the development of normal follicle by triggering a chronic inflammatory reaction and IR [8]. The gut microbiome is closely related to PCOS, but there is no consensus on which phylum or genera in gut microbiome is related to PCOS. The heterogeneity of PCOS is frequently reflected in many animal models. Therefore, if a rat model not only shows the characteristics of ovarian and metabolic syndrome, but also shows the dysbiosis of gut microbiota, it would be valuable for further study of new PCOS therapy. Testosterone has been proved to be related to the composition change of the gut microbiota [9]. Letrozole is a non-steroidal aromatase inhibitor, which can block the
conversion of testosterone to estradiol [10], and increase the testosterone level by increasing the production of ovarian androgen [11]. Continuous exposure to Dihydrotestosterone (DHT) can establish a PCOS rat model with typical hormonal disorders and ovarian morphological changes [12]. Excessive androgen secretion in early life may lead to hormone secretion disorder, which may lead to PCOS in adulthood [13-15]. In this study, female rats took DHT or letrozole continuously from before puberty, which led to adult PCOS rats.

**Materials And Methods**

**Animals**

Fifteen specific-pathogen free (SPF) level female Sprague Dawley (SD) weighting 50g± 5g, were aged 21 days at the onset of experiments. They were from the Experimental Animal Science Department of Guangzhou University of Chinese Medicine, Guangzhou, China (License number SCXK-2016-0168). The experimental protocols were performed after approval and in accordance with the guidelines set by the Experimental Committee of Guangzhou Medical University (Protocol number: GY2018-021). All rats were provided with humane care in a temperature-controlled room with a 12-hr light/dark cycle (lights on 07:00–19:00) and ad libitum access to food and water in their cages (22 °C–24 °C and 60% humidity).

**Study procedure**

Fifteen rats were randomly divided into three groups on average. According to previous studies [16,17], from 3w age, the rats in DHT group were subcutaneously injected daily with 83\(\mu\)g 5α-DHT which dissolved in 0.2ml tea oil for 6 weeks to mimic the hyperandrogenic state in women with PCOS. The rats in other two groups were injected daily with the same volume of tea oil alone. Follow the experiment of Kafali H et al [10], from 6week age, the rats in letrozole (LET) group were oral administration with letrozole (1mg/kg body weight of letrozole dissolved in 1 ml of 1% carboxymethyl cellulose (CMC) for 3 weeks. At the same time, the rats in control (C) group and DHT group were daily oral administration with 1 ml of 1% CMC. All the rats were fed commercial chow (Research Diets GB 14924.3-2010) [67% carbohydrate, 21% protein, 12% fat, and total 3.45kcal/g], was provided by Guangdong Medical Laboratory Animal Center.

**Vaginal smears**

The major cell type in vaginal smears obtained every day from 6 weeks old to the end of the experiment were analyzed by microscope to determine the periodic stage. Rats showing regular cycles of 4–5 days complete with the proestrus, estrus, metestrus and diestrus stages were defined as normal cyclic rats, whereas animals in which the estrus cycle was found arrested in any one of the stages for 4 consecutive days were termed as acyclic rats [18].

**Blood and tissue collection**
Blood was withdrawn through orbital sinus in a tube and separated by 10-min centrifugation (3,000 revolutions/min) at 4°C. Supernatant containing serum was separated and immediately stored at -20°C until analyzed for biochemical and hormonal analysis.

**Blood sampling for lipid profile, sex steroids and other biochemical parameters**

Fasting blood glucose (FBG) was analyzed by GOD-PAP. Testosterone (T), Free testosterone (FT), Fasting insulin (INS), Luteinizing hormone (LH), Follicle stimulating hormone (FSH), Superoxide dismutase (SOD), Malondialdehyde (MDA), Lnterleukin-22(IL-22), Lipopolysaccharide (LPS), Toll-like receptors 4(TLR4) and Tumor necrosis factor-α (TNF-α) were determined using enzyme-linked immunosorbent assay (ELISA) kit (mlbio, Shanghai, China). Sensitivity of methods are 0.1 ng/ml (FT, TLR4), 1.0 U/ml (SOD), 1.0 pg/ml (TNF-α), 0.1mU/L (INS), 0.1 pg/ml (IL-22), 0.1 mmol/ml (MDA), 1.0 pg/ml (T), 1.0 EU/L (LPS), and 0.1 mIU/ml (LH, FSH) at 95% confidence limit. Assays were performed according to manufacturers’ protocols. The optical density values were read at 450 nm using a microplate reader. HDL-C, LDL-C, total cholesterol and triglyceride levels were quantified by following the protocols provided with kits on UniCel DxC 600800 Synchron Clinical System. IR was appraised with the homeostasis model assessment of insulin resistance (HOMA-IR) method. HOMA-IR was calculated using the following formula:

\[
\text{HOMA-IR} = \frac{\text{FBG (mmol/L)} * \text{FINS (mU/L)}}{22.5}
\]

**Ovarian Histology**

The left ovary of rats was fixed in 4% paraformaldehyde and embedded in paraffin. 5 μm thick sections were prepared and stained with Hematoxylin-Eosin and histo-anatomical changes were observed and photographed under light microscope (BX-51, Olympus, Tokyo, Japan at ×40 magnification).

**16s rDNA sequencing data analysis**

The fecal microbiome for 15 fecal samples collected from 15 rats in the three groups. The 16S rDNA high through put sequencing (V3-V4 region) was performed using an Illumina MiSeq platform. After assembly, quality filtering and the random extraction of sequences at 97% similarity, the operational taxonomic units (OTUs) for species classification were obtained. The Chao1 and Shannon α-diversity indices were used to assess bacterial richness and diversity. In the aspect of β diversity, based on Bray-Curtis dissimilarity, permutational ANOVA (PERMANOVA) was used to assess bacterial community compositional difference. Linear discriminant analysis effect size (LEfSe) analysis coupled with the Kruskal-Wallis rank sum test was performed to identify the microbial differences among all groups. In LEfSe analysis, LDA effect size of >3 was used as the threshold.

**Statistical analyses**

Most statistical evaluations were performed with SPSS 20.0 for Windows (SPSS Inc., Chicago, IL, United States). All data were presented as mean± SEM. One-way ANOVA was used to determine the significance, p < 0.05 was considered significant. When the ANOVA revealed significant differences among three groups,
post hoc analysis was performed by a Tukey honest significant difference test. Kruskal–Wallis test was used for not normally distributed values.

Results

Animal characteristics

The weight of DHT and LET rats increased more than that of control group (ANOVA, P<0.01) (tab. 1). The concentration of HLD-C and the activity of SOD decreased in DHT group, compared with the C group. And the level of MDA in DHT group was higher than in LET group (p<0.05). Levels of T were similar in DHT rats and controls but were significantly elevated in LET rats (p<0.05).

Vaginal smears

The vaginas in all rats were mostly opened at the age of 40 days. The normal oestrus cycle of all control rats is 4~5 days, including proestrus, estrus, metestrus and diestrus. Vaginal smears of DHT and LET groups showed predominantly leukocytes, which indicated that they appeared continuously.

Ovarian morphological changes

A cystic follicle was considered to be a large fluid-filled cyst with an attenuated granulosa cell layer. Cross-sectional area of ovary was smaller in DHT rats and bigger in LET rats than in the controls. Light microscope observation showed that enlarged ovaries with multiple cysts in LET rats, while the ovaries of rats in DHT group had a tendency of follicle enlargement. The number of cystic follicles was increased with a relatively thin granulosa cell layer in DHT and LET rats compared with controls (Fig. 1).

The biodiversity in the gut microbiome

As shown in Fig.2, compared with the other two groups, DHT group had lowest Chao1 α diversity (p<0.01). The Shannon index in DHT group was significantly higher than the LET group (p<0.01), there was no significant difference between DHT and C group. Differences in microbial community structure between groups (β-diversity) were examined with PERMANOVA and visualized with PCoA plots (Fig. 3). At the taxonomic level of OTU, significant differences in microbial communities were observed between C and DHT rats (p = 0.006) and between LET and DHT rats (p =0.008). No significant difference was observed between C and LET group (p=0.054).(Table.2)

The microbial community structures at the phylum and genera levels

We evaluate the microbial composition by comparing the relative abundances of taxa at the phylum and genera levels. An overview of gut microbiota composition in each group at the phylum level was illustrated in Fig4. As shown in the Fig 5, compared with C group, a decrease in Bacteroidetes as well as an increase in Cyanobacteria, Tenericutes, Actinobacteria, Spirochaetae and Saccharibacteria in DHT group. No significant difference was discovered between C group and LET group.
LEfSe is a biomarker discovery tool for high dimensional data and used to determine which OTUs were differentially abundant between groups. The characteristic LDA discriminant histogram was used to calculate the significant gut microbiota between two groups to explain the consistency difference of relative abundance between the two groups. At genus level, the results showed that nineteen genera were obviously representative between DHT group and C group, with two (Vibrio and Catabacter) were more abundant in C group, and seventeen obviously changed genera (Lachnospiraceae_NK4A136_group, Ruminococcus_1, Ruminiclostridium, Anaerotruncus, Anaeroplasma, Acetatifactor, Treponema_2, Tyzzerella, Lachnolclosridium, Ruminococcus_2, Enterorhabdus, Coprococcus_1, Lachnospiraceae_FCS020_group, Streptococcus, Victivallis, Tyzzerella_3 and Marvinbryantia) were from DHT group. And four genera were distinctively represented between LET and C groups, with two (Peptococcus and Turicibacter) were more abundant in C group, and two (Vibrio and Bifidobacterium) were more abundant in LET group. (Fig6A-B and Fig7A-B).

Discussion

PCOS is a complex endocrine and metabolic disorder, which is related to ovulation dysfunction, hyperandrogenism, obesity and IR. Hyperandrogenism is a key feature of PCOS, and androgen may promote early follicular differentiation [20]. In present study, rats letrozole group exhibited endocrine and reproductive characteristics, such as hyperandrogenism, abnormal oestrus cycles or complete acyclic, polycystic ovaries, and obesity. DHT induced rats were showed obesity, irregular oestrus cycles, polycystic ovaries, lower level of HDL-C and lower activity of SOD than controls. Abnormal lipid metabolism is often present in women with PCOS, and its incidence rate is reported as high as 50% [21]. In PCOS patients, hyperandrogenemia is related to higher concentrations of plasma TG and lower HDL-C [22,23]. In our study, the DHT rats had lower HDL-C concentration than controls, while letrozole did not reduce HDL-C. Oxidative stress (OS) is defined as an imbalance in normal cellular environment, which is considered to be the cause of the development of many pathological diseases or deterioration of symptoms (such as inflammation) [24-26]. OS can also contribute to PCOS [27], the activity of SOD which related to the antioxidant capacity in DHT group was lower than in C group. We suspected that DHT may have a stronger and more direct role in regulating HDL-C and SOD activity than letrozole.

It is universally acknowledged that PCOS is a kind of complex heterogeneous disease [28,29], altered gut microbiome may be associated with the occurrence of PCOS [30]. Sex hormones play an important role on the gut microbiome of the host [31,32]. A study demonstrated that α diversity has a negative correlation with hyperandrogenism, total testosterone, and the other primary reproductive and metabolic characteristics of PCOS [10]. We evaluated two α-diversity indices, including the Chao 1 and Shannon index. The Chao1 index which accounted for richness of a community, DHT group owned the lowest richness of the gut microbiome in three groups. The Shannon index is an index that is commonly used to describe the species diversity in a community. No significant difference in Shannon index was observed between C and DHT rats, and between C and LET rats. But the Shannon index was significantly higher in DHT group than LET group. Alpha diversity analysis showed that the gut microbiota abundance and diversity in DHT group changed significantly. And the results demonstrated that the effects of DHT on gut
microbial community may be complicated. With respect to beta diversity, PCoA demonstrated significant differences between DHT group and the other two groups on the first axis, suggesting that the microbial community composition from LET group was more similar to C group and DHT could influence microbial community composition. Changes in gut microbial composition may be unfavorable, and lead to some diseases. In the field of ecology, species richness is considered to be related to ecosystem health, because diverse communities may improve the stability and productivity of an ecosystem [33]. According to several recent meta-analyses, compared with healthy individuals, it was also observed that a diversity of the gut microbiome reduced in human with metabolic diseases, which is related to human obesity [34-36].

DHT exposure altered the abundance of Bacteroidetes, Cyanobacteria, Tenericutes, Actinobacteria, Spirochaetae and Saccharibacteria. Bacteroides is involved in the metabolic process, which could absorb and metabolize polysaccharides, bile acid and steroids in foods that cannot be metabolized by the host. [37]. Turnbaugh et al. found that obese mice had more Firmicutes and less Bacteroides than lean mice, and that this distribution of gut microbiome can better absorb energy [38]. Bacteroidetes and Firmicutes are significantly related to metabolic syndrome, and the abundance of Bacteroides increased while that of Firmicutes decreased in exercise rats [39]. So, it showed that gut microbiome disorders may accelerate the process of DHT induced PCOS by affecting energy absorption, and appear obese. In addition, compared with C groups, DHT significantly increased the abundance of Actinobacteria, Cyanobacteria and Saccharibacteria. And the relative abundance of Actinobacteria and Saccharibacteria were significantly high in DHT group than LET group. The changes in the gut microbiota are related with specific metabolic states, such as obesity [40]. Actinobacteria was positively correlated with obesity [41], the high level of Actinobacteria aggravated the disorder of the intestinal flora and contributed to the progression from obesity to the related diseases [42]. Saccharibacteria are prominent in the oral cavity, and increased abundance of Saccharibacteria is correlated with the development of periodontitis [43] and inflammatory bowel disease [44]. However, the role of increased abundance of Saccharibacteria in DHT model rats are still unclear, which may be related to the inflammatory conditions. In order to identify the key bacterial genus in the gut microbiota, we used LEfSe multilevel species discrimination. The larger the LDA score shows the more significant the difference between the two groups. The results showed that Lachnospiraceae_NK4A136_group, Ruminococcus_1, Ruminiclostridium, Anaerotruncus and Anaeroplasma were abundant in the intestine of DHT induced PCOS rats. The Lachnospiraceae_NK4A136 group is an indicator of gut dysbiosis, because when present in great abundance, gut dysbiosis is more severe [45]. Ruminiclostridium has a significantly positive relationship with hyperglycemia [46], and was richness in DHT group. A study showed that the distribution and structure of the intestinal microflora (including Anaerotruncus) changed after ovariectomy in rats [47]. Anaerotruncus was significantly positively correlated with ovary weight [48], which might be in line with rats’ ovaries enlarged in our study. In addition, an increased relative abundance of Anaerotruncus species is related to aging and age-associated inflammation with elevated pro-inflammatory chemokines in a mouse model [49]. Interestingly, as a taxa of the family Ruminococcaceae, genus Ruminococcus_1 is one of the dominant butyrate-producing bacteria [50]. Anaeroplasma is considered as a potential anti-inflammatory probiotic.
for treating of chronic intestinal inflammation [51], but an increased relative abundance of *Ruminococcus_1* and *Anaeroplasma* were observed in DHT group. In line with that, the concentrations of TNF-α and IL-22 were similar in C group and DHT group.

According to the score of LDA, compare with LET group, *Peptococcus* and *Turicibacter* were more abundant in C group. *Peptococcus* is a Gram-positive bacterium commonly found in digesters, and was positively correlated with butyrate [52]. Butyrate is a short-chain fatty acid, which is helpful for maintaining cellular health by inhibiting the expression of pro-inflammatory cytokines in the intestine through mechanisms including nuclear factor kappa B signaling [53]. *Turicibacter* was also reported to be related to anti-inflammatory properties [54-55]. The interesting finding was the higher abundance *Bifidobacterium* in LET group than in C group. *Bifidobacterium* a traditional probiotic, which can ameliorate visceral fat accumulation and insulin sensitivity in an experimental model of the metabolic syndrome [56]. *Bifidobacterium* is also considered as a potential candidate drug for treating obesity [57], and is known to enhance intestinal integrity [58].

In a word, our findings indicate that DHT affects the composition and diversity of gut microbial community, and leads to the gut dysbiosis. Letrozole may benefit to the gut microbiome in some aspects, but it also may have a trend of inhibiting the expression of some anti-inflammatory genera in intestinal tract.

**List Of Abbreviations**

Polycystic ovary syndrome (PCOS), androgen dihydrotestosterone (DHT), letrozole (LET), Luteinizing hormone (LH), Follicle stimulating hormone (FSH), Testosterone (T), Free testosterone (FT), Fasting insulin (INS), Fasting blood glucose (FBG), Homeostasis model of assessment for insulin resistance index (HOMA-IR), High-density lipoprotein cholesterol (HDL-C), Low-density lipoprotein cholesterol (LDL-C), Total triglyceride (TG), Total cholesterol (TC), Toll-like receptors 4 (TLR4), Lipopolysaccharide (LPS), Superoxide dismutase (SOD), Malondialdehyde (MDA), Interleukin-22 (IL-22), Tumor necrosis factor-α (TNF-α), insulin resistance (IR), principal co-ordinate analysis (PCoA).

FIG4. A bar plot about the microbial community structures at the phylum level.
FIG4. A bar plot about the microbial community structures at the phylum level.
Fig 5. Box-plot of comparing the relative abundance between groups at the phylum level. *: compare with C group, p <0.05; **: compare with C group, p<0.01.
Fig 5. Box-plot of comparing the relative abundance between groups at the phylum level. *: compare with C group, p <0.05; **: compare with C group, p<0.01.
Figure 6

Differentially abundant OTUs between C group and LET group using LEfSe analysis. A: Taxonomic cladogram of differences in the gut microbiota, green shows taxa enriched in C group, red shows taxa enriched in LET group, and yellow indicates no significant. The diameter of each circle is proportional to the abundance of taxon. B: The most abundant taxa in C group with green histogram and LET group with red histogram (LDA > 2 logs).
FIG 7. Differentially abundant OTUs between C group and DHT group. A: Green shows taxa enriched in C group, red shows taxa enriched in LET group, and yellow indicates no significant. The diameter of each circle is proportional to the abundance of taxon.

FIG 7.B: Differentially abundant OTUs between C group and DHT group using LEfSe analysis. B: The most abundant taxa in C group with green histogram and DHT group with red histogram (LDA > 2 logs).

Figure 7
FIG7. Differentially abundant OTUs between C group and DHT group. A: Green shows tax enriched in C group, red shows tax enriched in LET group, and yellow indicates no significant. The diameter of each circle is proportional to the abundance of taxon.

FIG7.B: Differentially abundant OTUs between C group and DHT group using LEfSe analysis. B: The most abundant taxa in C group with green histogram and DHT group with red histogram (LDA > 2 logs).
